The introductory chapter summarises the results of the inquiry, and recommends the development of international collaboration by the foundation of an international series of courses or conferences, attached to a university or an institution controlled by some national authority, for the purposes of further research in library economy, as an experimental measure, the necessary finance being assured by Governmental subventions from all interested parties. A bibliography of twenty-six pages, geographically arranged, is not the least valuable section of this work, which should be found on the shelves of every library anxious for the betterment of itself, its staff and its service to the community. B. M. HEADICAR.

Technical Aspects of Emulsions:
being the Papers read at a Symposium held in London, December 7th, 1934, under the auspices of the British Section of the International Society of Leather Trades' Chemists. Pp. vi+150. (London: A. Harvey, 1935.) 6*s*. net.

THE twelve sections of this book concern the physical chemist, the physician, the patent agent, the engineer, and the technologist in many industries (laundry-work, agriculture, food-preparation, woollen-textiles, varnish, leather, rubber, bitumen).

Diversity was the aim of the symposium and the book is witness to the attainment of that aim. This prompts the thought that, in books of this kind, there may be a place for the thread of unity which runs through diversity. The reviewer turned to the first section, that on the mechanism of emulsification, hoping there to find that thread traced through the other papers. He found, instead, a stimulating account of the effect of ultra-sonic waves in making and breaking emulsions: a piquant *hors d'œuvre*.

Diversity without unity has its drawbacks. Words are used loosely. On p. 93 the word 'nucleus' means the oily part of mayonnaise emulsified with some of the aqueous part thereof. The physicist uses the word in another sense, the biologist in yet another. Perhaps there is not much harm done; but there may be some. Dialects tend to be both used and confused. From confusion to obscurity is but a step. The passage at the bottom of p. 4 is rather near obscurity: "A device of this kind might be characterised by the fact that the droplets formed travel parallel to another with different velocity along a too great a distance and that this may cause an orthokinetic coagulation".

Nevertheless the sections of the book are well written. That is the reason why a faulty passage strikes the eye. Some sections are good descriptive catalogues with references by the hundred; others have a philosophic turn; yet others are both bibliographical and philosophical; all are illuminating; one is of outstanding interest, namely, that on the use of highly dispersed emulsions in the treatment of toxæmic conditions. The compilation is the record of an important symposium meant to be diverse in treatment. F. S. A.

Mathematik im Dienste der nationalpolitischen Erziehung mit Anwendungsbeispielen aus Volkswissenschaft, Geländekunde und Naturwissenschaft: ein Handbuch für Lehrer. Herausgegeben im Auftrage des "Reichsverbandes Deutscher mathematischer Gesellschaften und Vereine" von Adolf Dorner. Pp. iv+118. (Frankfurt am Main: Moritz Diesterweg, 1935.)

THIS book is intended to provide teachers of mathematics with examples connected with the aims of the National Socialist Government. The book is not a persistent exposition of the logic of any part of pure or of applied mathematics. It is a collection of detached chapters, explaining in words various matters which both interest the Nazis and are capable of simple quantitative treatment. Formulæ which are important are stated; but mostly without proof. Numerous examples are given, with algebraic or arithmetical answers.

The remarkable aspect of the book is the selection of subject matter. Broadly, one may say that there are 59 pages of social statistics and 49 pages of military geometry. In the statistical part one finds explanations of means, standard deviations and correlations; also treatments of life-insurance, of savings banks, of Mendelism, of unemployment, of the birth-rate, of trade and food supply. At the end of the book there are 15 pages of German statistics. An interesting diagram (on p. 23) shows the great contrast between the age-distribution of Germans in 1931 with that in 1910.

The part of the book here described as military geometry deals with map-reading, with aerial navigation, with protection against bombs dropped from above, with the paths of projectiles *in vacuo* and in air, also with sound-ranging. Except for these, the ordinary applications of mathematics to mechanics and to physics are notably absent. The words *Stimme* and *Wahl* (= vote, election) do not appear in the index. L. F. R.

A New Angle on Health

(Nature's Provision for the Health and Happiness of Mankind). By Surg.-Capt. D. H. C. Given. Pp. xvii+160+5 plates. (London: John Bale, Sons and Danielsson, Ltd., 1935.) 7*s*. 6*d*. net.

THE author of this book was for more than eight years stationed at Singapore, and this he claims has given him a unique opportunity to contrast the health of a primitive Asiatic community of diverse races with that of naval personnel and white civilians. He finds that the physical standard of the Asiatic labourer is *A* 1, as compared with the *C* 3 standard of civilisation, that his teeth are on a par with his physical standard, and that he does not suffer from the diseases common among Western races.

It is to be noted that in the Asiatic labourer of Singapore, the author is dealing with a very selected and restricted group, which cannot be compared with our own population as a whole. Similarly, when it is stated that in contrast to the European, the epidemic influenza in the Asiatic in 1931 was mild and free from complications, it should be recalled that India and South Africa suffered some years ago from a devastating epidemic of influenza, and this disease in native races is not necessarily a mild one; in fact, one epidemic may differ entirely in severity and in incidence from another one.

Basing his arguments on what in many instances we believe are faulty premises, the author attributes the ills from which we suffer to the effects of urbanisation, overcrowding, extremes of poverty and riches, the decline of agriculture, and under- and improper feeding—much of which is doubtless true—and condemns our Western civilisation as being founded on selfish greed, industrialism and parasitism. He concludes that so long as selfishness continues to dominate the lives of men, so long will the human race fail to realise the happiness for which it strives, and that the precepts of Christianity form the only basis of a healthy and happy life. R. T. HEWLETT.

Technics and Civilization

By Lewis Mumford. Pp. xi+495+16 plates. (London George Routledge and Sons, Ltd., 1934.) 18*s*. net.

THIS book provides an interesting and thought-provoking contribution to the history of the machine and its sociological effects on humanity. Mr. Mumford divides the machine age into three great periods: (1) the 'eotechnic' based on animal, water and wind power; (2) the 'paleotechnic' which came in with Watt's steam engine and had its basis in coal and iron, and (3) the 'neotechnic' which is now dawning and promises industrial decentralisation, cleanness, leisure and abundance, its basis being the long-distance transmission of electric power.

Discussing the assimilation of the machine, Mr. Mumford points out that as machinery was developed, attention came to be centred more and more on the product, people valuing the machine for what it produced. The machine thus appeared purely as an external instrument for the conquest of the environment to the neglect of the actual forms of the products, the actual collaboration and intelligence manifested in creating them and the educational possibilities of this impersonal co-operation itself. The objects rather than the spirit that produced them were assimilated, and so far from respecting that spirit, the aim was to make the objects themselves seem to be something other than the product of the machine. The industrialists and engineers themselves did not believe in the qualitative and cultural aspects of the machine. The possibility that technics had become a creative force which was rapidly ordering a new kind of environment and producing a third estate midway between Nature and the humane arts, was far from the minds of those who actively promoted the mechanisation of production.

The Recollections of a Geographer

By E. A. Reeves. Pp. 224+8 plates. (London: Seeley, Service and Co., Ltd., n.d.) 8*s*. 6*d*. net.

AFTER fifty-five years service in the Royal Geographical Society as map curator and instructor in surveying, Mr. Reeves retired in 1933. Many hundred travellers and explorers have owed to him all they knew of survey work, so that his influence has reached to every corner of the globe. Here are glimpses of men like Stanley, Bates, Burton, Nansen and many others who brought their observations and discoveries to the Society.

Mr. Reeves has anecdotes about many and a kindly word for all. He has allowed no adverse criticism to appear in his pages; but he has clearly omitted many of his experiences, for the book is not long as a record of half a century of noteworthy people. A hurried sketch of the progress of exploration and survey in that period is included as well as some account of Mr. Reeves's own work on magnetism and in the improvement of surveying instruments. Finally, there is an unconvincing chapter on the author's psychic experiences.

It is a kindly and ingenuous book that to many will recall a teacher of great ability and untiring patience, and to others will appeal as a sketch of fifty years of discovery as seen from the Royal Geographical Society, by the one man above all others who has directed exploration.

Diesel Engine Design

By Harold F. Shepherd. Pp. vii+277. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935.) 17*s*. 6*d*. net.

THE Diesel engine has now been constructed successfully in so many different types that any book on its design which is not restricted to one particular line of development must almost necessarily become too discursive to be of practical value to the designer. It is in this respect that H. F. Shepherd's "Diesel Engine Design" fails to meet the real need for a book or series of books on this subject. The historical and descriptive treatment and the discussions on numerous points which arise in design are all to the good; but the author does not really grapple with the actual problem of design until the last chapter or two. It is an introduction to, rather than a manual on, design. J. A. C.

Wave Action on Vertical Wall Breakwaters

By Dr. Brysson Cunningham

THE efficacy of the resistance to wave action of vertical wall breakwaters built on a rubble mound foundation has been called into question recently by reason of two unfortunate, and, in fact, structurally disastrous, incidents which have been experienced, at Catania in Sicily in March 1933 and at Algiers in North Africa in February 1934. The matter is one of fundamental importance, since quite a number of important harbours in the Mediterranean and elsewhere are protected by breakwaters of this type. It was discussed at considerable length by an eminent Italian engineer, Prof. E. Coen Cagli, in a lecture which he delivered lately at the Institution of Civil Engineers, a short reference to which was made in NATURE of July 20, p. 99.

The vertical wall breakwater is, in principle, a homogeneous or at any rate, so far as may be practicable under the conditions of the site, a coherent structure, generally formed of prismatic concrete blocks properly coursed and bonded, in contrast to the mound breakwater which consists essentially of a mass of rubble stone of various shapes and sizes deposited more or less at random on the sea floor and sometimes surmounted by heavier artificial units. The two types are, therefore, strikingly different in character, though it is rare to find a pure example of either, since the rubble mound is frequently capped with a coping course and parapet of blockwork, whereas the wall, when the site is in water of considerable depth, has generally to be founded on a bed of rubble, on account of subaqueous constructional difficulties and also from motives of economy. Moreover, at a certain depth below the surface, it is known that wave action ceases to produce any appreciable disturbance in a rubble mound foundation.

By way of illustration, it may be said that the harbours of Dover, Tynemouth and Peterhead in Great Britain are of the vertical wall type, while an excellent example of the mound type is to be found in the outer breakwater, or "Grand Jetée", at Marseilles.

Until comparatively recently, despite its importance from a scientific as well as a practical point of view, experimental research into the phenomena of wave action had not been conducted on any systematic lines. It is true that individual observations have been recorded from time to time and valuable deductions made therefrom by several scientific writers, but from lack of official co-operation and financial assistance the data so obtained have been somewhat fragmentary and incomplete. It is satisfactory to note that at the port of Genoa a very efficient apparatus is now installed for the purpose of taking continuous records. Into the outer breakwater at a suitably exposed point has been built a special monolith, or hollow block (Fig. 1) containing apparatus whereby at a series of successive levels ranging from 10 metres below to 3 metres above sea-level, piezometric values of wave stroke are recorded both mechanically on the spot and also by electrical transmission to a wave oscillation register situated in the sheltered area of the inner harbour. By means of this apparatus a number of valuable pressure records and 'oscillograms' has been obtained and described by Dr.-Ing. Salvatore Levi[1]. An account of the installation has been published by Commendatore Ing. Albertazzi, the Chief Engineer of the port[2].

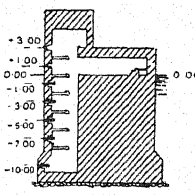

FIG. 1. Wave pressure recording monolith at Genoa.

It is not proposed in this article to discuss the numerical values of wave pressures recorded by this and other means, but to direct attention to the general principles and conditions of stability of vertical wall breakwaters in the light of the instances of failure which have occurred at Catania and Algiers. I had an opportunity, while in Sicily recently, of discussing the former breakwater with Signor A. D'Arrigo, who was associated with its construction, and last year, at Algiers, I similarly discussed the causes of the collapse of the second arm of the Mustapha Jetty with Monsieur P. Rénaud, the Engineer and Port Director there.

To commence with, it is to be noted that there was an essential difference in construction between the two breakwaters, cross-sections of both of which are given in Figs. 2 and 4. Both were founded on rubble mounds, the first (Catania) at a depth of 12·5 metres below sea-level, and the other (Algiers) at 15 metres below sea-level; but, whereas the Catania mole consisted of a series of disconnected piers, 12 metres in transverse section, made up of 320-ton concrete blocks, each 12 metres by 4 metres by 3·25 metres, unbedded and unconnected in any way by cement joints or reinforcement, the piers of the latter, 11 metres across in transverse section, were welded into a

monolithic whole by means of vertical wells, or shafts, filled with concrete reinforced by steel bars.

Now as to the circumstances of collapse. While in course of being lengthened, the Catania mole had already suffered damage from an east to south-east storm (without wind) on February 22, 1930, which engendered waves of 7 metres height and 200 metres length. Some horizontal displacement of the courses took place and there was also a vibratory motion observed, due to the uplifting action of the waves on the underside of the blocks, and that this was the primary cause of fracture.

In the case of the Mustapha Jetty, on the other hand, the monolithic piers of which it was composed remained intact under wave impact until they were finally overturned. The north-easterly tempest of February 2–3, 1934, which caused the

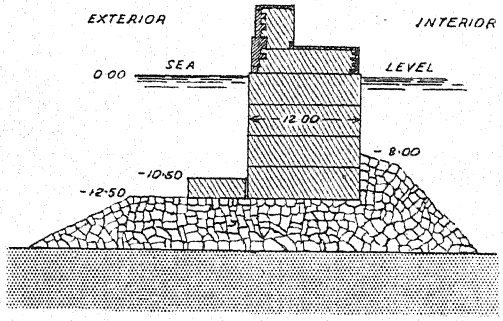

FIG. 2. Catania breakwater as constructed.

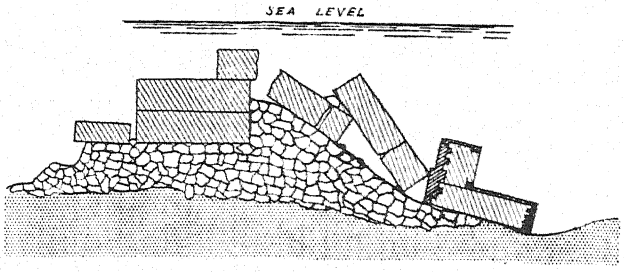

FIG. 3. Catania breakwater after demolition.

a part of the work was dismantled. The damage, however, was made good without any change in the design, beyond raising the platform on the harbour side by a height of 1 metre, with the view of increasing the load on the piers. The first arm of the jetty had then been built out to its full length when another storm of more exceptional severity from the north-east, with waves 7·5 metres in height and 230 metres in length, broke on March 26, 1933, and completely demolished the work for a length of 700 metres, the parapet wall and successive layers of blocks above the two lowermost courses being swept into the harbour, in some cases a distance of as much as 40 metres, and more or less fractured and disintegrated. It is to be noted, as can be seen in Fig. 3, that the blocks in the process of displacement slid over one another, due to the lack of adhesion at the joints. Signor D'Arrigo states that collapse of 401 lineal metres of the mole, was accompanied by waves of 9 metres height and 300 metres length[3]. The vehemence of the wave stroke, however, failed to overturn the wall by direct impact, to which effective resistance was offered for many hours. Failure, when it occurred, was due to the powerful suction of the recoiling waves, which drew down the rubble mound and scoured out a trench in the sea floor at the foot of the wall, into which the latter subsided, as shown in Fig. 5, and then disintegrated. There is every probability that had the rubble mound been able to resist the suction of the 'back-draught', the wall itself would have come through the ordeal with but slight, and certainly not irreparable, damage.

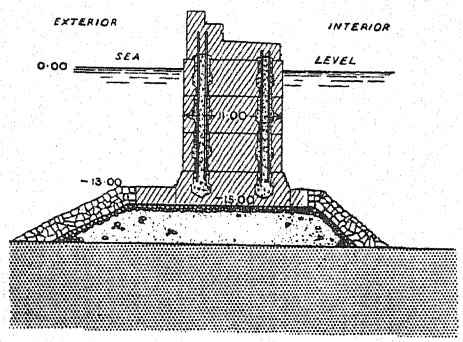

FIG. 4. Mustapha Jetty, Algiers, as constructed.

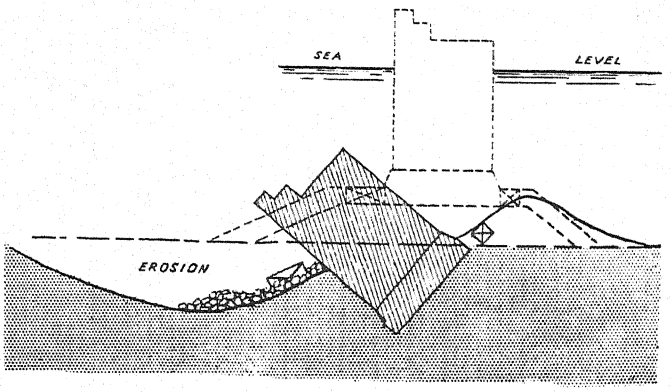

FIG. 5. Mustapha Jetty, Algiers, showing process of collapse.

The view expressed in his lecture by Prof. Coen Cagli, who, it should be stated, was mainly responsible for the introduction into Italy of the

vertical wall breakwater, is that neither of these untoward incidents justifies a condemnation of the type, which in every case other than Catania in Italian seas, has demonstrated a satisfactory stability. This view commends itself as perfectly reasonable and Prof. Cagli is fully justified in maintaining, that if, in the case of the Catania breakwater, the wall had been monolithic in structure instead of consisting of a vertical series of disconnected blocks, imperfectly bedded; and if, in the case of the Algiers breakwater, the rubble mound foundation had been made sufficiently resistive to suction and undermining, neither of the storms, despite their unprecedented severity, would have been likely to produce the serious results which actually occurred. It has been decided, however, that both breakwaters are to be reconstructed as rubble mounds without vertical wall superstructures. In the case of the Algiers mole, this was perhaps inevitable from a consideration of the nature of the sea floor and the accumulation of debris from the old work.

In consonance with a resolution passed at the fourteenth International Congress of Navigation at Cairo in 1927, a special committee of experts from various countries, including Sir Leopold Savile as representative of Great Britain, has been engaged in investigating the problem of wave action, and the installation at Genoa above referred to constitutes one of the avenues of research. Prof. Cagli has himself been conducting a series of experiments with small-scale models in co-operation with Prof. A. Stucky at the Hydrological Laboratory of the University of Lausanne. The results obtained from the tests carried out up to the present were given by Prof. Cagli in his lecture, and they may be briefly summarised as follows:

(1) The complete agreement of the actual pressures recorded at Genoa with those obtained by means of tests on the model of the Principe Umberto Mole at that port indicates, on one hand, that the method of research by tests on small-scale models, based on the law of mechanical similitude, is strictly applicable to the study of wave stroke, while, on the other hand, it demonstrates, contrary to the opinion expressed by some writers on the subject, that oscillating waves, in violent storms at any rate, are not converted by reflection at a vertical wall into actual 'standing waves' (Ital.: *onde stazionarie*; Fr.: *clapotis*), but maintain their essential trochoidal characteristics with a modified orbital movement and that they exert pressures which notably exceed those of actual standing waves of the same magnitude. For example, it was found that the total effort at Genoa of a normal wave of 5 metres height and 110 metres length exceeds by 26 per cent the total effort which would be exerted by a standing wave engendered by the same ordinary wave and having therefore the same length with twice the height.

(2) The tests on a small-scale model of the Mustapha Jetty at Algiers have demonstrated (Fig. 6) that under the terrific conditions of the storm of February 3, 1934, with waves 9 metres high and 185 metres long in the immediate vicinity of the work, the wall experienced a total pressure of 147 tons per lineal metre of structure, which is greater by 35 per cent than the pressure which would have been exerted by a standing wave of the same length and 18 metres high. As a consequence of this effort, the intensity of pressure on the rubble mound along the inner edge of the wall base should have amounted to 8·25 kgm. per sq. cm. (about 7½ tons per sq. ft.); certainly an excessive load, but one which, very likely, was not actually realised to the full calculated extent by reason of the intervention of certain impedimentary factors, such as the continuity of the mass concrete capping of the breakwater and the rise of the water inside the harbour as a result of the rise of level outside.

(3) The model of the Catania mole having, in turn, been subjected to the impact of waves 7·50 metres high and 155 metres long adjacent to the structure, similar to those observed in the storm of March 26, 1933, the result of the tests (Fig. 7) showed that the wall experienced a total pressure of 129 tons per lineal metre of structure, producing an intensity of pressure on the rubble foundation of 6·70 kgm. per sq. cm. (say, 6 tons per sq. ft.); a pressure which the wall, 12 metres thick, would clearly have withstood better than

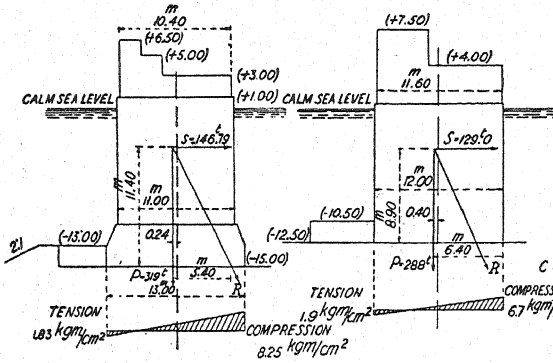

FIG. 6. Stability diagram, Mustapha Jetty, Algiers.

FIG. 7. Stability diagram, Catania breakwater.

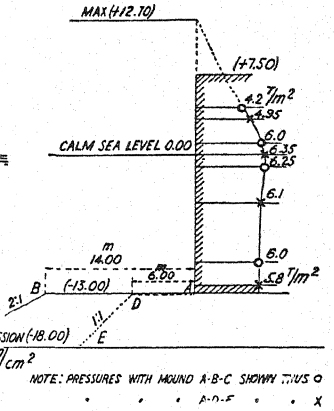

FIG. 8. Pressures exerted by wave 6·50 metres high, 155 metres long.

the Algiers mole if it had been monolithic in character.

(4) The results of the whole series of experiments on small-scale models have enabled it to be established that the intensity of pressure exerted against a vertical wall by oscillating waves diminishes progressively above smooth sea-level in the ratio of two thirds of the height above this level. Thus, with a surface level pressure of 6 tons per square metre, at a height of 3 metres the pressure would be reduced by 2 tons to 4 tons per square metre. The pressure diagram is, in fact, substantially a triangle with a base angle of about 60°.

(5) In none of the tests with small-scale models relating to wall breakwaters at Genoa, Algiers and Catania, standing in depths of 15, 21 and 18 metres respectively and having their wall bases located at levels of − 10, − 13 and − 10·50 metres respectively, could waves of the maximum observed heights of 7, 9 and 7·50 metres be caused to break, even superficially, in front of the wall, although given an increase in length in the open 'sea' beyond admissible proportion, that is, up to forty times their height. In every case, in fact, there was produced a maximum unitary effort, almost exactly uniform over the whole immersed section of the wall and equal, as in all the other experiments, to the hydrostatic pressure corresponding to the height of the waves. It is therefore justifiable to conclude that if the depth of the sea at the site of the work exceeds, as is usually the case, twice the height of the greatest storm waves to be expected in the locality, and if the base of the vertical wall lies at a depth of one and a half times the same height, there should be no danger of waves breaking completely against the work. Moreover, it has been possible to ascertain that under these conditions, the width of the benching at the foot of the wall and the inclination of the side slope do not affect in any way the intensity of stroke exerted by the waves against the wall (Fig. 8).

While under the foregoing conditions it is permissible to exclude the risk of complete breaking of the heaviest storm waves against the work, it is not impossible, however, that during storms accompanied by very strong wind, the waves, retarded in their propagation by the progressive decrease in sea depth and by the effect of the slope of the rubble foundation, may, under the influence of the wind, break superficially and so produce against a part of the face of the wall pressures which are more intense than would be those exerted by the same waves if they remained purely oscillating up to the moment of contact. Unfortunately, no observations or experiments so far made have provided data for the estimation of the intensity and distribution of these exceptional pressures, so that no precise indication can be given of the additional strength required to withstand such shocks. However, it is to be noted, on one hand, that waves accompanied by strong wind are sensibly shorter than waves of the same height propagated in the entire absence of wind, with the consequence that the total effort exerted against the wall is considerably less in the first than in the second case ; and, on the other hand, that the effort exerted by the breaking wave, which is purely dynamic and exhausts itself in a comparatively short time, affects the resistance of the wall to shear much more than to overthrow or slip. It follows, adds Prof. Cagli, that if the work be designed with the requisite margin of safety for withstanding oscillating waves of the maximum height for the locality, unaccompanied by wind, the monolithic structure of the wall, or its component piers, may be deemed sufficient to ensure the requisite stability in the event of an augmented stroke from waves of maximum height which happen to break superficially in approaching the wall during storms accompanied by strong winds.

Such are the results obtained from the experimental study of wave action on small-scale models, and while Prof. Cagli admits that they may not be considered exhaustive, they afford useful guidance in dealing with wave action in relation to structures of the vertical wall type[4].

Speaking in general terms, as the outcome of a consideration of the disasters at Catania and Algiers, it would appear from the former that despite the difficulties arising from unequal settlement in a rubble foundation, a continuous monolithic wall is better adapted to withstand the known characteristics of wave stroke than a wall of detached superimposed blocks, even of cyclopean magnitude ; and from the latter, that the action of the recoiling wave on the rubble mound and a soft sea bottom requires very careful consideration. Hitherto, it has been held with a certain amount of justification that the undulatory movement of the sea (which extends on a decreasing scale to considerable depths) is not likely to have much, if any, depreciatory effect on a rubble mound lying at a level of about 40 ft. below the surface of the sea. At Algiers the rubble mound was seriously disturbed and the sea floor eroded at depths considerably greater, even approaching double the figure in question. It seems essential, therefore, for complete security that the recognised standard should be reconsidered, and an appreciably increased depth adopted in situations where the 'fetch' is sufficient to promote the generation of waves of the order of 25–30 ft. in height and 500–600 ft. in length.

An Ancient Chinese Treatise on Alchemy

By Prof. J. R. Partington, M.B.E.

ONE of the early Chinese texts on alchemy is the *Ts'an T'ung Ch'i* of Wei Po Yang, who has been called the father of Chinese alchemy. His treatise has been regarded as the earliest work in the Chinese language which is devoted exclusively to the subject, although it is by no means the earliest Chinese writing which makes mention of alchemy. It shows, in fact, that a definite and extended tradition of alchemy was in existence when it was written, and it mentions several earlier alchemists who are otherwise known, either from their own writings or from notices in Chinese historical works. It seems reasonable to conclude that, for two or three centuries before Wei Po Yang, the Chinese had been engaged in an attempt to transmute base metals into gold, not because gold was intrinsically valuable but because of the supposed magic efficacy of artificial gold in prolonging life. This belief is found also in ancient Egypt[1] and is no doubt based on the unalterable character of the noble metal. The Chinese believed that an artificial gold could be prepared from cinnabar (mercuric sulphide) which would have a more powerful action than natural gold.

The early Chinese alchemical works attach considerable importance to the synthesis of cinnabar from mercury and sulphur and its resolution into its constituents[2]. These operations also attracted considerable attention among the early Egyptian alchemists, the oldest of whose works, extant in Greek, are supposed to go back to the early centuries of the Christian era[3], but may be based on texts a century or so earlier. Since Wei Po Yang lived in the second century A.D., and since alchemists are mentioned in Chinese records two or three centuries before this, it is evident that the origins of alchemy in China and in Hellenistic Egypt are practically contemporary. The oldest known works in both cases are of approximately the same date, and in both cases they mention earlier works and traditions—sometimes fabulously early.

It is, therefore, very difficult to decide with our present information whether the origins of alchemy in Egypt and China were independent or not, and, if they were, which was earlier in date. An Arabic origin of Chinese alchemy, on the other hand, although it has been suggested, seems very improbable, since a knowledge of alchemy did not reach the Arabs from Egypt until several centuries after we find alchemy well known in China. A common origin of Chinese and Arabic alchemy is quite possible.

Wei Po Yang was a Taoist philosopher, and the development of alchemy in China was almost certainly closely connected with the later developments of Taoism[4]. He was born in the province of Kiangsu, and in the year 121 A.D. was summoned to the Court, but declined the invitation, having no liking for officialdom. He describes himself in the epilogue of the *Ts'an T'ung Ch'i* as "a lowly man who has no love for worldly power, glory, fame or gains", but content to spend his life in peace in a retreat in an unfrequented valley —definitely Taoist sentiments. His work is one of the Taoist classics, and is still read in China. It purports to be a commentary on the old Chinese classic, the *Book of Change*, but is really a treatise on the preparation of the elixir, or pill of immortality. Chinese works say Wei Po Yang and three disciples went to the mountains to prepare this, and when it was made he tried it on a dog, which died instantly. Wei Po Yang then asked what should be done, whereupon the disciples suggested that he should try it himself. He did so, saying that it would be a disgrace to live if the preparation of the medicine had failed through lack of concoction, and he also died instantly. One disciple then said: "Our teacher is no common person. He took the medicine and died of it. He must have done that with some special intention." He also took the medicine and died. The other two disciples then left to arrange for the burials, but when they had gone Wei Po Yang revived, and resuscitated the disciple and the dog with some of the well-concocted medicine; they all went the way of the immortals, leaving a note with a wood-cutter for the other two disciples.

Wei Po Yang's treatise has been translated by Dr. Lu-Ch'iang Wu and annotated by Prof. Tenney L. Davis[5], the translation being preceded by an interesting general discussion. It states that the *Book of Change*, the Taoist doctrines and alchemy are merely three variations of the same thing under different names. It makes use of the early Chinese philosophical conceptions of the *Wu-hsing* (five elements: wood, earth, water, fire and metal) and *Yin-Yang* (two contrary principles). The words *yin* and *yang*, originally meaning dim or obscure, and bright, respectively, later took on the meanings of numerous pairs of opposites. Thus, *yang* meant the sun or male principle and *yin* the moon or female principle, the interaction of which produced the five elements, each identified with a planet. Dr. Wu and Prof. Davis point out that this doctrine of two contraries dominated

chemistry for a long period, and it may be suspected that it lingers in forms not mentioned by them even at the present day. Dr. Wu suggests, in opposition to generally received opinion, that the notion of *yin* and *yang* is not purely Chinese, that it came with the occult doctrines associated with it from some other civilisation, possibly from Babylonia or Egypt, and perhaps alchemy came with it at the same time. "But the search for the elixir of immortality seems to bear no necessary relation to the occult doctrine of the contraries, and we are unwilling to conclude that the two necessarily derive from the same origin." It is suggested that there is a clear and natural affinity between Chinese alchemy and Taoism : if alchemy did not originate out of Taoism, the latter at least "supplied a congenial medium for the growth of alchemical ideas". This theory has, in fact, seemed probable to a number of former investigators[2,4].

The translation of the *Ts'an T'ung Ch'i*, which Wu and Davis divide into sixty-nine chapters, shows that it is, as we should expect, an obscure and mystical work. It contains a number of subtle ideas and is enlivened by a sense of humour and an absence of egotism which contrast favourably with the writings of the Arabic and later European alchemists. Of positive chemical knowledge, such as we frequently find in the Greek alchemists[3], there is very little, if any. An insistence upon secrecy is found.

As a specimen of the theoretical speculations in the *Ts'an T'ung Ch'i*, the following may suffice :

Chapter 18. "One, knowing the white, should hold firm to the black. For then divine light will come in due course. The white is the essence of gold and the black is the basis of water. The water is the control of the *Tao* and is one in number. At the beginning *yin-yang* is black, and with yellow sprouts, the master of the five metals and the river chariot of the north. Hence lead is black on the outside but holds gold flower in its bosom."

Those who are familiar with the Greek chemical texts will find many points of contact between the ideas in them and those of the above and many other passages in the Chinese text. The formation of litharge from lead is probably indicated.

As a specimen of the description of practical operations, the following may be quoted :

Chapter 64. "Above, cooking and distillation take place in the cauldron ; below blazes the roaring flame. Before goes the White Tiger leading the way ; following comes the Grey Dragon. The fluttering Scarlet Bird flies the five colours. Encountering ensnaring nets, it is helplessly and immovably pressed down and cries with pathos like a child after its mother. Willy-nilly it is put into the cauldron of hot fluid to the detriment of its feathers. Before half the time has passed, Dragons appear with rapidity and in great number. The five dazzling colours change incessantly. Turbulently boils the fluid in the furnace. One after another they [the dragons ?] appear to form an array as irregular as a dog's teeth. Stalagmites, which are like midwinter icicles, are spit out horizontally and vertically. Rocky heights of no apparent regularity make their appearance, supporting one another. When *yin* and *yang* are properly matched, tranquility prevails."

We have here a fairly clear account, as alchemical literature goes, of some process of solution and crystallisation.

Chapter 66. "White at first and then yellow, it finally becomes red on the outside and on the inside. This is called the first furnace and it is as large as a grain of millet. All this is the work of nature and has nothing to do with untoward doings. It is like the fact that the *ch'i* (ethereal essence) of the mountains and the waters rises to give clouds which then become rain. Again, it is like the reduction of mud to give dust and the destruction of fire to give earth. The bark of the *nieh* tree dyes yellow and the *lan* (indigo) dyes blue ; the boiling of hides yields glue, and the *ch'ü nieh* yeast ferments to give liquor. It is easy to get results when the starting materials and the desired products are of the same kind. Otherwise it is very difficult."

Many points of contact between these and other statements in the Chinese treatise and in the Alexandrian Greek treatises can be found, so that the general conclusion of Dr. Wu and Prof. Davis, who do not favour much relation, is scarcely borne out by detailed examination : they cite, in fact, several parallels with Zosimos in the notes and could have cited a good number more. These notes suggest parallels with later works on European alchemy, and there is an index of (transliterated) Chinese words.

Dr. Wu and Prof. Davis are to publish later some alchemical chapters from Ko Hung, a celebrated Chinese Taoist philosopher and alchemist of the fourth century, and the history of chemistry will be enriched by their work. The translation of these early texts is a difficult task, from which previous sinologists have turned away in something like despair, but there is nothing like making a start. Criticism and improvement can follow this, but they do not precede it.

Obituary

Mr. C. E. Stromeyer

HALF a century ago the practices used in the design and construction of industrial boilers left much to be desired in the way of scientific treatment, and it is no exaggeration to say that Charles Edmond Stromeyer, as chief engineer to the Manchester Steam Users' Association, was a leading spirit in the process of transforming the existing art into something approaching an exact science. The reason is not difficult to find, since he possessed an inborn capacity for investigation and research, to which was added the experience gained during seventeen years as an engineer surveyor to Lloyd's Register of Shipping. During that persistent endeavour, which occupied thirty years, the city of his adoption was a centre of interest for those engaged on the construction and maintenance of boilers, for engineers from distant lands frequently called upon him—and the pilgrimage continued after the year of retirement, in 1928. For this reason, a wide circle of friends must have welcomed the honorary degree of Dr. Ing. that was conferred last year by the Technische Hochschule at Aachen on its old graduate.

It is strange to recall that Stromeyer's apprenticeship was terminated due to an incapacity for further manual labour, since up to a few weeks before his death at Bad Nauheim, on July 23, in his eightieth year, he daily attacked the work that lay before him in the study and the laboratory. As a further indication of this unceasing activity of mind and body, it may be remarked that the manuscript of his "Unity in Nature", which may still be read with much pleasure and profit, was written *en route* during bi-weekly journeys between Manchester and London in the years preceding the War, when he was much occupied on professional and scientific affairs in London. Not the least important of those interests were matters connected with the foundation of the National Physical Laboratory.

Since he belonged to a generation that regarded education mainly as a training for independent thinking, Stromeyer's contributions to the proceedings of the Royal Society and our senior engineering and naval institutions almost invariably formed milestones by the way of progress in his sphere of interests. The ground included in that sphere was extensive, as he made the first direct determination of Poisson's ratio, used his interference strain indicator to measure the stresses on ships and the strains on railway bridges in the 'eighties, and contributed an instructive paper, on map-projection, to the International Geographical Congress held at Berlin in 1900. His work on the fatigue of metals is of outstanding merit, and the involved investigations doubtless gave rise to an original contribution presented in 1907 to the Manchester Literary and Philosophical Society, in which the atomic weights of the elements were expressed in the form of a harmonic series. In view of such a wide and deep knowledge of natural philosophy, it is in the nature of things that his "Marine Boiler Management and Construction" should have attained a sixth edition, apart from foreign translations of the volume.

With his intense devotion to work, anything short of transparent honesty met with Stromeyer's strongest disapproval, and he considered no weapon too heavy to handle in the defence of what appeared to be the right course of conduct. That characteristic must have served him well during the War period, in undertaking the exacting duty of examining and reporting on the safety of secondhand boilers that would not have been used in other circumstances.

To those who were privileged to know him intimately, Stromeyer's cultured and attractive outlook on life was a constant source of pleasure, as the labour of the day never seemed to tire the boyish spirit that was the deep-seated source of his activity. The welfare of his assistants was as real a concern to him as was their success in professional affairs, and they, along with many others, will place him in that small company of whom it may be said that they were "Servants upon horses, and princes walking as servants upon the earth". In that role his charming wife bore him faithful company. D. L-T.

Dr. Arthur Bramley

THE death of Dr. Arthur Bramley on July 19 deprives chemical and metallurgical science of a brilliant worker. Born in 1878, he was forced to leave school early, and served a full apprenticeship to the hosiery trade. He commenced his technical education in Halifax Technical College, and in 1904 obtained a staff appointment there. This was followed in 1906 by a national scholarship of the Royal College of Science where he graduated, carried out research work and finally became private research assistant to Prof. J. C. Philip. With the latter he conducted a number of researches on the physico-chemical properties of solutions and ionic complexes the results of which are published in the *Journal of the Chemical Society*. He then proceeded to investigate the physical properties of binary liquid mixtures, for which work he was awarded the degree of D.Sc.

The second phase of Dr. Bramley's service to science commenced with his appointment to the technical staff of British Dyestuffs Corporation at Huddersfield, where he remained until he was appointed to take charge of the Department of Pure and Applied Science, Loughborough College, in 1918. At Loughborough he commenced a long series of researches on the diffusion of non-metallic elements into iron and steel and was able to show that the mechanism of this diffusion follows the normal physico-chemical course. These researches, published over a period of fifteen years, obtained for

him the award of the Carnegie Gold Medal in 1929.

Apart from his research work, Dr. Bramley was an enthusiastic teacher and had been instrumental in building up an active Pure Science Department in Loughborough College; his untimely end cut short a career which had promise of even greater fruition.

We regret to announce the following deaths:

Dr. R. W. Brock, dean of the Faculty of Applied Science in the University of British Columbia, known for his work in economic geology, on July 31, aged seventy-one years.

Prof. B. L. Robinson, emeritus professor of systematic botany in Harvard University, an authority on the classification of American spermatophytes, on July 27, aged seventy years.

Mr. W. T. H. Spicer, formerly first ophthalmic surgeon at St. Bartholomew's Hospital, known for his work in connexion with the teaching of ophthalmology, on August 8, aged seventy-four years.

Mr. A. H. Swinton, a well-known naturalist, author of "Insect Variety, its Propagation and Distribution", on July 25, aged ninety-one years.

News and Views

Archæology in the Cambridge Fens

In another column of this issue of Nature (see p. 304) there appears a brief account of the results of tree pollen and vegetation analyses of peat deposits in the Cambridgeshire Fens. The borings by which the material for these was obtained were made in connexion with an archæological excavation undertaken with the object of establishing the stratigraphical position of prehistoric cultures of mesolithic and bronze age, of which surface indications appeared on this site at Peacock's Farm, Shippea Hill, Cambridge. The archæological results, based on the stratigraphic evidence, taken in conjunction with the evidence of the botanical investigation, have a far-reaching significance. A succession of three cultural horizons has been established, Early Bronze Age, Neolithic and Late Tardenoisian. The demonstration of such a succession on one site in a single vertical section is unique. Further, the association of each with a definite forest growth and vegetation context—a microlithic industry is here found in a peat deposit for the first time in Britain—opens the way to a number of precise chronological and cultural correlations. Hereby this Late Tardenoisian site is linked up with other finds in Britain, such as that at Skipsea, Yorks, and with Continental sites, such as Maglemose, Mullerup and Kunda.

In other directions, also, this excavation has established important criteria for future investigation. Thus Neolithic *A*, the Windmill Hill culture, appears in this part of the country for the first time, not far removed from sites of Neolithic *B*, "Peterborough", finds. The application of the method of pollen analysis to the latter, when occasion arises, no doubt at an early date, should settle definitely the, at present, uncertain chronological relations of the two cultures. Mr. J. G. D. Clark's skilful reconstruction of the history of the site—a history of shrinkage of the area of settlement from period to period owing to the encroachment of the peat, with long periods of inactivity intervening—is an achievement which will hold a permanent place in the history of archæological investigation.

Excavations at Maiden Castle, Dorchester

Excavations have been resumed at Maiden Castle, Dorchester, under the direction of Dr. R. E. Mortimer Wheeler, the initial objective being the investigation of the history of the ramparts. Digging at a point where the rampart rises to a height of fifty feet above the external ditch has revealed that the structure was composed of a core of carefully built up chalk rubble, faced on the inner side, covered with a layer of clay and chalk and surmounted by a parapet of limestone. The parapet was partially destroyed in ancient times, and eventually replaced by a timber palisade of which the socket holes have been found at a higher level. This palisade was constructed of stout timber posts at a distance of four or five feet apart and doubtless joined by woven hurdles. A cutting which has been made through the main defence shows evidence of five prehistoric periods in the history of the earthwork, the earliest being a palisaded bank of about ten feet, and culminating in an elaborate structure of masonry rising twenty feet above the internal camp. Beneath the original turf line a stone age factory floor was uncovered, on which were innumerable flakes from implement making, and a few scrapers and other tools. On an adjacent site a series of pits has been found, of which one is nine feet deep. These pits contained prehistoric pottery and a number of querns for grinding corn. Nearby was a group of ten loom-weights of chalk; and in the centre of this site post holes indicate the position of a large circular hut twenty-one feet in diameter. Finally, at the east gate of the camp three roads of late-Roman and post-Roman date have been examined and prehistoric road level has been reached.

Unknown Papua

Some further particulars of the hitherto unknown people found in Papua by Mr. J. G. Hides (see Nature, August 17, p. 251) are given in extracts from the official report and an article by the Australian correspondent of *The Times* in the issue of August 14. The report stresses the interest of the people in afforestation, the exactness of the division of the

fields for cultivation into squares and the straightness of the field drains, ranging from eight to ten feet in depth, the mode of burial in the open in wooden coffins surrounded by a picket fence, and the non-Papuan character of the people, shown especially in the lightness of their colour, their high cheekbones and finely moulded features. It is stated that, while anthropologists hesitate to express any opinion, owing to the lack of confirmation on investigation of previously reported marvels from the interior of Papua, Mr. E. W. P. Chinnery, Government anthropologist of Papua, has suggested their identity with the unknown tribes of Mount Hagen discovered in 1932 by Messrs. J. L. Taylor and M. Leahy (see NATURE, 134, 328; 1934). Mr. Hides, however, maintains that he has discovered a new people, but identifies tribes whom he afterwards encountered to the south-east with the people of Mount Hagen. His own theory is that the light-skinned people escaped years ago up the limestone cliffs after defeat in battle by other tribes and, discovering this fertile valley, settled, multiplied, and developed an entirely self-contained community. Until photographs are available, no judgment is possible, and until much more is known of the physical characters of the inhabitants of Papua, there is little utility in the discussion of theories of the survival of races. In the meantime Mr. Leahy and his brother confidently claim priority of discovery, and assert that light-skinned natives, common to many tribes, are pathological cases and usually exhibit symptoms of a mild form of St. Vitus's dance. Mr. M. Leahy, it is reported, is now on his way to submit photographs, films and other data to the Royal Geographical Society.

The Ovada Disaster

ONE of those calamitous occurrences which, from time to time, show the fallibility of human judgment in constructional work, has plunged northern Italy into desolation and mourning. Shortly after noon on August 13, a dam, which formed in the valley of the River Orba in Piedmont near the town of Ovada, the artificial lake, or reservoir, of Orsiglieto, containing a volume of 78,000,000 cubic feet of water, suddenly gave way and the impounded water, thus released, swept through the valley, destroying entire villages and causing widespread havoc and destruction. The number of lives lost is probably several hundred, and has been put so high as a thousand; but, in the absence of official statement, this estimate should, perhaps, be accepted with reserve. Four bridges were broken, one of them a railway bridge which collapsed a few minutes after a passenger train had passed over it. Nearly two miles of track has been torn up. The other three bridges were highway structures. Traffic was cut off, and telephonic and telegraphic communications interrupted. The flooded zone extended over an area about $2\frac{1}{2}$ miles long and $1\frac{1}{2}$ miles wide. It is stated that the disaster was the culmination of a series of violent thunderstorms which broke over southern Piedmont and central Liguria during the night of August 12 and the morning of August 13, and that in the Ovada region, adjacent to the dam, the precipitation reached the intensity of a 'cloudburst', converting streams and watercourses into raging torrents. The damage is roughly estimated in the neighbourhood of a million sterling. The dam, which is part of the undertaking of the Genoa Electrical Co., was built twenty years ago. Official instructions have been issued for its reconstruction.

Sir John Colbatch

UNDER the title of "An Early Forgotten Antiseptic Surgeon", who, as he maintains, has been most unjustifiably neglected by surgeons and medical historians, Prof. D. F. Fraser-Harris (*Med. Press and Circ.*, June 19, pp. 580–82) gives an account of John Colbatch, the author of a work published in 1704 entitled "Novum lumen chirurgicum or a New Light of Surgery wherein is Discovered a much more Safe and Speedy way of Curing Wounds than has hitherto been Practised". In this book, Colbatch describes the virtues of a "vulnerary powder", with which he had dressed wounds so successfully that in about four days all putrefaction was stopped. The composition of the powder he kept secret, and thereby incurred the reputation of a quack; but his comparison of its odour to the smell of roses suggested to Sir Watson Cheyne that it was ammonium salicylate. The chief scientific interest of Colbatch's work lies in the fact that, in addition to relating in detail the histories of fourteen cases of severe wounds in Flanders, where he was on military service, treated by the powder, he states that he performed experiments on about a hundred dogs to test its value, and was thus one of the earliest surgeons to experiment in the modern sense of the term. The date of Colbatch's birth is uncertain, but he died at an advanced age on January 15, 1729. He was knighted by George I in 1716.

Work of the Mellon Institute

THE twenty-second annual report of the Mellon Institute of Industrial Research, covering the period 1934–35, refers to extending activities in scientific, as well as in industrial, research. It is expected that the new building will be gradually occupied during 1935 and be complete by the end of the year. 62 industrial fellowships were in operation during 1934, requiring the services of 97 fellows and 48 assistants. 56 of these fellowships were in operation at the end of the year, and a high proportion of the fellowships are of five or more years standing. New fellowships during the year dealt with starch, stone, dried yeast, soya bean, etc., while fellowships terminated during the year covered cleaning, sugar, velvet, phosphates, paper finishing and vanadium. Special attention is directed to the studies on cinchona alkaloids conducted by the Department of Research in Pure Chemistry with the object of discovering compounds of therapeutic value in pneumonia. Fifty-nine such preparations have been tested, and biological and clinical data are being accumulated, some of which have been published. Studies on the preparation of apoquinine and its ethyl and hydroxyethyl ether are

practically ready for publication. A research on the action of sodium and sodamide has been completed and the preparation and alkylation of cinchona alkaloid oxides is being studied.

ON the industrial side, important results have been obtained in fundamental research on carbon blacks. These have led to the development of a method for the colloidal dispersion of carbon black pigments in lacquer vehicles, which gives black lacquers of markedly improved properties. Other fellowship studies have shown that, by the use of aqueous dispersions of carbon black, maximum darkening of concrete can be obtained with a minimum (2 per cent) of pigment, with as much as 25 per cent greater strength in the concrete. Aqueous dispersions of carbon black for these purposes are being sold under the name 'Hiblak'. Other researches have led to the development of a new enamelling process, new building materials, including improved plastic cements and new sulphur cements for use as binding agents or protective coatings in structures subjected to acids or corrosive solutions. New methods for testing refractories have been developed while the fundamental investigations on sodium hexametaphosphate which have led to the development of 'Calgon' have been continued. Under a fellowship for organic synthesis, methods for the preparation of glycol ethers have been developed and improved, new types of vinyl resins examined, and a group of polyethyleneamine derivatives of ethylenediamine has been developed for use in gas purification. New uses for ethylene and morpholine amines have been discovered, and important work on dental caries and on atmospheric pollution has also been carried out.

President Masaryk and Technology

UNDER the title "T. G. Masaryk a Technika" the Masaryk Academy of Work has published an account of President Masaryk's contacts with science and his keen interest in the technical applications of pure science. It will be recalled that his early experiences at the blacksmith's forge proved of value to him in after life when he was professor of philosophy and later still in his capacity as President of the Czechoslovak Republic. Quite early in his university career, he drew up a classification of the sciences (afterwards much used and adapted on the Continent), dividing them into theoretical (abstract and concrete) and practical. He placed them into seven groups, showing their mergings and affinities. Without being a specialist in any branch, Prof. Masaryk was well versed in scientific method and became something of an expert in detecting forgeries. He endeavoured to direct his philosophy and science towards improving the amenities of mankind. Two quotations from his writings make clear his attitude. "In former times we went after things which struck our fancy, we went in search of gold, the philosophers' stone, the elixir of life. Now we analyse water, air, the soil, manure, everything ordinary that surrounds us." "Without work we shall never have sufficient self-confidence. Work alone shows us what we are capable of. Work is self-recognition." The main part of the publication "T. G. Masaryk a Technika" has been compiled by Dr. V. Škrach; but a section on the origin of the Masaryk Academy of Work in 1920 is contributed by Prof. E. Zimmler, a former chairman. The Academy was founded as an autonomous scientific institution to organise technical work, making the best use of scientific advances and the natural resources of Czechoslovakia. It is composed of six sections: biological science and medicine, agriculture and forestry, building science, mechanics and electro-technics, chemistry and national economy. In its programme the Academy has combined all branches of engineering with the sciences, and has attempted to correlate research work and advances in the different sections so that they can be put to technical applications with the least possible delay.

Longer Trade Cycles

IN a pamphlet entitled "The Longer Trade Cycles" (Almquist and Wiksells Boktryckeri A-B., Stockholm, 1935), Axel F. Enström claims that a sixty year oscillation can be traced in a large number of price movements and production processes. An investigation of coal price quotations is said to have shown a complete sixty year period extending from about 1850 to 1910, while an examination of Sauerbeck's index number curve for wholesale prices disclosed the same cycle and in addition pointed to an earlier cycle of probably the same length. Valuable data illustrating price variations over a very long period, going back as far as the thirteenth century, are to be found in the Vicomte D'Avenal's monumental survey of French wheat prices, and an analysis of this material, according to Mr. Enström, shows a series of cycles of the order of magnitude of 60-50 years. If the D'Avenal curve is examined in the light of purely qualitative evidence which Free-being Swedish and European history as a whole can give regarding economic events in the eighteenth and nineteenth centuries, it will be found that the twenty-year period of the curve accurately reflects the original fluctuations in the European trade situation. The great technical inventions have as a rule been achieved in those periods which correspond with periods of depression in the superposed trade curve, that is, in periods characterised by a low price level.

Recent Developments in Genetics

THE Nobel lecture given by Prof. T. H. Morgan at Stockholm on June 4, 1934, is printed in the *Scientific Monthly* of July 1935. In it Prof. Morgan reviews the progress of genetics, with special emphasis on recent developments. The nature of the gene is discussed, the position each occupies in the chromosome being regarded as probably in the nature of a historical accident. Linkage, translocation, the pairing of chromosome threads and the recent work on salivary gland chromosomes all yield evidence regarding the nature of the genes, but the manner of their growth and division remains hidden. The physiological properties of the genes and their

relation to development are discussed at length. That embryological differentiation is not a sorting out of genes is clear, but present evidence is insufficient for deciding between various possible views of the ways in which the genes control development. (1) All genes may be active all the time, producing different results by their action on different parts of the egg cytoplasm. (2) Different batteries of genes may come into action at different stages of development, or at different rates, as Goldschmidt has postulated for sex-genes. (3) Possibly the kind of activity of the genes changes in response to the kind of protoplasm in which they lie. Finally, the relation of genetics to medicine is touched upon, and the importance of the developments in human genetics is recognised in relation to the inheritance of human defects, mental and physical. It is predicted that hundreds of cases of genetic linkage in man will be discovered.

Teaching the Value of Forests

ONE of the troubles in connexion with forestry and afforestation in Great Britain is the loss by the population of what, for want of a better term, has been termed the 'forestry sense'. Out in the Empire the difficulties of the forest officer arise from other causes. In each case it is sought by propaganda and education to teach the people the true value of the forest and its position in the economic structure of nations and the lives of the population. The Forestry Department in Trinidad is issuing a series of Forestry pamphlets "for teachers". No. 3 of the issue (Trinidad: Government Printer, Port-of-Spain, 1934) is entitled "Timber: Its Structure, Properties, Seasoning and Preservation" by Mr. R. L. Brooks, the conservator of forests. The pamphlet is illustrated by simple diagrams.

OF a somewhat different type, but having the same object in view, is the handbook to a temporary exhibition (May–September) based on the tree collections in the Department of Botany in the National Museum of Wales. This small brochure is entitled "Some Aspects of Forestry in Wales" (Cardiff 1935). The handbook has been prepared by Mr. H. A. Hydes. In a preface, Dr. Cyril Fox, the director of the Museum, writes: "The Forestry Act of 1919 authorised the formation of large State Forests and has thus broadened immeasurably the basis of forest ownership. Every man is now an owner of plantations, and should have some idea of how and why they are created and maintained. Such problems as the relative values of broad-leaved trees and coniferous trees as forest crops, and the scenic effect of planting introduced species along with native trees, which are now freely discussed in the Press, can only be understood in the light of at least a minimum of knowledge of the species concerned and of their relation to forestry in general." The exhibits are set out under the headings: Welsh forest botany, forest operations, forest pathology, wood anatomy and utilisation of forest produce. Among interesting exhibits are those relating to the beautiful woods of the Wye Valley, afforestation of sand dunes in South Wales, and the well-known plantations at Lake Vyrnwy, the chief reservoir for supplying water to the city of Liverpool. Those plantations now amount to 4,500 acres out of the total area of 5,000 acres which it is proposed to plant.

Literature of the Occult

ALTHOUGH the consideration of magic is a necessary prelude to the study of primitive religion, and, as such, lays claim to no inconsiderable share in the literature of anthropological science, it forms relatively only a small proportion of the vast accumulation of printed matter which has grown up in relation to magic in the larger sense, more especially in connexion with its manifestations in belief, theory and practice in medieval and modern times. Excepting historical and descriptive treatment, scientific analysis of this mass of material has barely begun. Eventually, when its evidence has been sifted and subjected to test, it should provide a valuable corpus of reference in the scientific investigation of manifestations of the 'marvellous'. In the meantime, a comprehensive library of occult literature is indispensable to research, especially in the detection of fraud. Unfortunately, the works which contain contemporary or early records of the facts are often both rare and costly. The University of London Council for Psychical Investigation is fortunate in having at its disposal the library of occult literature formed by Mr. Harry Price, from which a selection of five hundred rarities was on exhibition in December last (see NATURE, Dec. 15, 1934, p. 927). In 1929 Mr. Price published a catalogue of the greater part of his library, which contained 10,000 items. To this he has now added a supplement containing an additional 2,500 items acquired since that date (University of London Council for Psychical Investigation, Bull. 1: "Short-Title Catalogue of Works on Psychical Research . . . : From 1472 A.D. to the Present Day", pp. 112. London: 13D Roland Gardens. 2*s*. 6*d*.). It is embellished with nine illustrations, title-pages or cuts from rarer books such as Molitor's "De Lamiis et Pythonicis Mulieribus" (c. 1489) or "The Famous History of Friar Bacon" (1660), "very pleasant and delightful to be read" as is recorded on the title-page.

Power Farming in India

THE Imperial Council of Agricultural Research in India has issued, as Scientific Monograph No. 9, a report by C. P. G. Wade, on mechanical cultivation in India, prefaced by an approving foreword and an introduction, written by agricultural officers of the Government. The publication of the report in this form is of special interest, for the work has been inspired, financed and largely carried out by a commercial organisation, the Burmah-Shell Oil Storage and Distributing Co. It is difficult to see how the Government could have given official approval to work of this nature without raising awkward questions of precedent and policy, but for the existence of the Council, the constitution of which, as drawn up by the Linlithgow Commission on Indian Agriculture, was kept flexible and free from

certain restrictions necessarily observed by Government departments. Much of the work was done co-operatively with the agricultural departments of Provincial Governments. The scheme of work was conceived on broad and public-spirited lines; the Company cannot hope to recover its expenditure by any immediate increase in sales of oil; the most it can expect is to share, in common with other industries, in the increased general prosperity that will accompany any lasting improvement in the agricultural conditions of rural India. Although the greater proportion of Indian cultivators farm under peasant conditions, and cannot directly take up power farming, the question of co-operative use is worthy of attention; in addition, there seems a much larger scope for heavy power machinery on large holdings, for example, planters' estates, and in the reclamation and improvement, under Government supervision, of large areas. The report deals in detail with an extensive series of experiments on weed eradication by deep cultivation, on contract ploughing and on the analysis of costing data. The concluding chapters are devoted to a discussion of the design and performance of tractors and cultivation implements in relation to Indian conditions, and to the organisation of contract tractor ploughing.

Annual Report of Cheshunt Experimental Station

THE twentieth Annual Report (1934) of the Experimental and Research Station of the Nursery and Market Garden Industries Development Society, Ltd., has recently been published, from the Station, Turner's Hill, Cheshunt, Herts (pp. 107). The experimental work for 1934 is a continuation of the previous trials of varieties, fertilisers, soil heating, methods of sterilisation and other practices. Mycological investigations include a considerable section on virus diseases, and studies of fungi which attack chrysanthemums, roses, lettuce, carnations and other crops. A new insect parasite of the tomato moth caterpillar has been further described, pests of lettuce and chrysanthemum have received special study, whilst the more common thrips, symphilids and woodlice have also had attention. Insecticide and fungicide investigations have been continued, and the chemists have inquired into the potash content of 'blotchy' tomatoes and the manurial nutrition of chrysanthemums. The effects of light and water content on the growth of tomato plants, with studies on vernalisation, form the main subjects of physiological interest.

Use of Radium in Ireland

THE Irish Radium Committee has issued its report for the year 1934 (*Sci. Proc. Roy. Dublin Soc.*, **21**, No. 25, 1935. Separate issue). There was a small increase in the number of batches of radon tubes issued; but a decrease in the total quantity of radon, owing to the continued tendency towards the use of smaller doses, and a considerable increase in the number of cases treated. Little can be gathered from the report of the success or otherwise of the treatment, and an unsatisfactory feature is the fact that some 25 per cent of the patients treated could not be traced after their discharge from hospital.

Prof. P. O. Pedersen

THE friends of Prof. P. O. Pedersen, principal and professor of electrotechnics of the Royal Technical College, Copenhagen, have published in English some of his papers written in Danish to commemorate his sixtieth birthday, which occurred on June 19, 1934. The subjects discussed are mainly on the development of electrical communication technique, with special reference to contributions by Danes. Excellent work has been done by Gulstad, L. Lorenz, Jensen, C. E. Krarup, Johnsen and Rahbek, Valdemar Poulsen and Prof. Størmer. In a lecture delivered in 1933, Pedersen discusses the possibility of an application of scientific technical methods to other fields of research. The last paper given is on the depreciation of public utilities. In an appendix, a list is given of 97 publications by Pedersen.

New Discoveries of Permian Insect Fossils

ACCORDING to Science Service, Washington, D.C., an extensive deposit of fossil insects has been brought to light in a sandstone stratum near the mouth of the Mezer River on the Arctic coast of the U.S.S.R. A preliminary study of these remains has been made by Prof. A. G. Martynov, who finds that all Palæozoic families of insects are represented. Cockroaches are most abundant, but grasshoppers, dragonflies, scorpion flies and other primitive insect groups are also well represented, together with a small number of Coleoptera. An expedition of the Russian Academy of Sciences is at present making collections and studies in the region mentioned. It appears that these insect beds are contemporaneous with the well-known insect-bearing strata of Kansas, which have yielded an abundant fauna.

Japanese Biological Publications

WE have received vol. 3, Nos. 1 and 2 of *Botany and Zoology, Theoretical and Applied*, from Japan. It is a monthly publication, and these two numbers contain 364 and 176 pages respectively. The papers are illustrated and cover every phase of biology, but with the exception of one paper by Prof. Crozier, of Harvard University, they are entirely in Japanese. Only the scientific names and the names of Western authors are given in European characters, except one paper printed in Japanese using the Western alphabet! It seems a pity that papers, many of which are evidently of considerable general interest, should thus be cut off from Western science. Even Esperanto, which is occasionally being used by the Japanese in their scientific publications, would be preferable as a medium of publication if it is intended to attract the interest of biologists outside Japan.

Scientific Research in Australia

THE eighth annual report of the Commonwealth of Australia Council for Scientific and Industrial Research shows an increasing range of investigation and a growing number of requests for assistance

and advice. The difficulties which the Council had to face in its early years have now been largely overcome, and research stations have been provided and staffed, and are in full activity. The range of problems covers plants, insects, animal nutrition, soil, irrigation, forest and cold storage problems, all of which are important to Australian prosperity. The fear that activity would have to be curtailed owing to financial stringency necessitating a reduction in the Council's grant has been largely obviated by the readiness with which funds have been given by corporations, commercial companies and private persons.

Bibliography of Greenland

A BIBLIOGRAPHY of works on Greenland confined to authors born in Norway, as well as Icelandic authors prior to 1814, has been compiled by Mr. H. Vartdal and published as No. 54 of the *Skrifter om Svalbard og Ishavet*. The list runs to nearly eight hundred entries, and subsequent to 1721 is arranged according to subjects. A full index facilitates use. The list certainly has value, but would have been far more useful if it had been compiled without reference to the nationality of the authors, since the greater part of the works on Greenland are by Danish writers.

Bibliography of Seismology

MR. ERNEST TILLOTSON, 23, Roseville Road, Leeds, 8, writes with reference to notes on this subject in NATURE of June 29, p. 1070, and July 27, p. 138, that he has received from Mr. Ernest A. Hodgson, the author of the "Bibliography of Seismology", a number of forms to fill in with details of British publications on seismological subjects. With the aid of these forms, he hopes to keep the "Bibliography" as up to date as possible so far as authors normally resident in the British Isles are concerned. To this end Mr. Tillotson asks such authors to send to him at the above address any newly published seismological literature. It is probable that, whilst papers and books on seismology in the narrower sense have been included in the "Bibliography" already, papers on seismological prospecting or on such subjects as changes in level, or the growth of faults, or earthquake insurance, etc., may have been overlooked.

International Navigation Congress

THE sixteenth International Navigation Congress, which is to be held at Brussels on September 2–13, under the patronage of H.M. the King of the Belgians and the presidency of the Minister of Public Works, will discuss a number of questions and communications relating to inland and maritime navigation, including the regulation and treatment of rivers and canals and the protective works required at ports and harbours. The Belgian Government has invited all the States interested in the Association of International Navigation Congresses to send official delegations to Brussels for the occasion. The Secretary General of the Association is M. Joseph Millecam, 38 rue de Louvain, Brussels, from whom full particulars can be obtained of the meetings, and of the excursions to various installations and undertakings in Belgium and Holland.

Announcements

THE National Trust has accepted an offer by the Countess Buxton of nearly 150 acres of the South Downs at Newtimber Hill. The gift includes down and mixed woodland (mainly beech) with exceptionally fine views to the north and west, including Chanctonbury and Cissbury Rings.

THE fifteenth International Congress of Medical Hydrology, Climatology and Geology will be held at Belgrade in October 1936 under the patronage of the Prince Regent. Further information can be obtained from the general secretary, Prof. M. Neskovitch, 3 rue Takowska, Belgrade.

THE second International Congress of Mental Hygiene will be held in Paris on July 27–31, 1936, with Prof. H. Claude as president of honour and Dr. E. Toulouse as president. The official languages will be French, English, German, Italian, Spanish and Portuguese. Typewritten copies of communications must be sent to the president of the executive committee, Dr. René Charpentier, 119 rue Peronnet, Neuilly-sur-Seine, France, not later than November 1, 1935. The subscription, which is 125 francs, should be sent to the treasurer, M. R. Demaclus, 27 rue de Londres, Paris.

THE first number of a new quarterly, *Annals of Science*, devoted to the history of science since Renaissance times, will be published by Messrs. Taylor and Francis, Red Lion Court, E.C.4, on January 15, 1936 under the editorship of Dr. D. McKie of University College, London, joint author of "The Discovery of Specific and Latent Heats"; Prof. Harcourt Brown, of Washington University, St. Louis, U.S.A., author of "Scientific Organisations in 17th Century France"; and Mr. H. W. Robinson, assistant librarian of the Royal Society of London, co-editor of "The Diary of Robert Hooke".

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A junior scientific officer (physicist) at the Fuel Research Station, East Greenwich—The Establishment Officer, Department of Scientific and Industrial Research, 16, Old Queen Street, Westminster, S.W.1 (Aug. 27).

A research chemist in the Department of Agriculture, Straits Settlements and the Federated Malay States—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1. (Aug. 31).

A lecturer in the Civil and Mechanical Engineering Department of the Woolwich Polytechnic, S.E.18—The Secretary (Aug. 31).

An assistant lecturer in agriculture to the Cornwall County Council Education Committee—The Secretary, Education Department, County Hall, Truro (Sept. 10).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 303.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Statistical Tests

As the originator of the P, χ^2 test, I should be glad if you can spare me space for some reply to Mr. Buchanan-Wollaston[1]. I should like first to state that I am in no way responsible for all the applications which have recently been made of that test, and do not accept the validity of some of the applications which Prof. R. A. Fisher has made of it in his well-known textbook. I am not concerned with his position and leave him to defend it. My own position is as follows:

(i) I introduced the P, χ^2 test to enable a scientific worker to ascertain whether a curve by which he was graduating observations was a reasonable 'fit'. On this account, and as a measure of success in graduation, I termed it a 'goodness of fit' test. It had no special relation to the normal curve or to any other curve. The scientific worker in the past had chosen any curve he pleased to graduate his observations, but he rarely applied any measure of its aptness, beyond looking at a graph to 'see' whether it was a 'good fit'. The pages of the Royal Society *Transactions* and *Proceedings* are evidence enough of this fact.

(ii) As a measure of 'goodness of fit', the P, χ^2 test does enable one to compare the relative advantages of any two graduation curves. But I personally have never assumed that the better graduation curve was the one from which the material had actually been drawn.

(iii) I have shown both theoretically and experimentally that there is a high correlation between the 'goodness of fit' of a graduating curve to a *sample*, and the 'goodness of fit' of that curve to the parental population from which the sample has been drawn. Accordingly, *if the sample be large*, the graduating curve may be taken as representing reasonably the parent population.

(iv) I have shown that, when dealing with *small* samples, no real distinction can be made between sampling from, say, a normal curve or a rectangle. It requires at least a sample of more than a 100 individuals to determine whether it would be best to use a rectangle or some other curve! I have repeatedly insisted that little can be learnt of the superiority of one graduating curve over another, if the sample be not of considerable size, say, well beyond the 100 mark.

All this proves that the P, χ^2 test has no relation to Mr. Buchanan-Wollaston's remark that: "The fact that British methods 'work' is due to the prevalence in Nature of distributions *similar* to the Gaussian [*sic*] rather than to any peculiar virtue in the methods themselves". It would appear from this remark that my critic and his 'Continental workers' have never gone beyond applying the test to questioning whether the normal curve was a reasonable graduation curve!

(v) The only relation of the P, χ^2 test to the normal curve arises from the use of that curve in the analysis to replace binomials by normal curves. Such replacement is not legitimate *theoretically*, when in the binomial $(p + q)^n$, p is very much larger or very much smaller than q. This has led to the practice of clubbing together small 'tail' groups. But practically there is, *as a rule*, very small difference in the resultant P's, whether we club tail groups and reduce the number of cells, or work P out for the full number after considering outlying individuals which may be anomalous. I do not therefore understand Mr. Buchanan-Wollaston's remark that: "It seems only reasonable that but a small part of the centre of the χ^2 distribution should be used as a test of *fit*". In a large percentage of cases to which χ^2 may be applied in biometric and biological investigations, there are no 'tails', that is, no small categories at the terminals. If we wish to avoid the assumption that at such 'tails', where they exist, it is legitimate to replace binomials by normal curves, then the P, λ_n test can be applied.

(vi) From my point of view, the tests are used to ascertain whether a reasonable *graduation* curve has been achieved, not to assert whether one or another hypothesis is true or false. If we narrow ourselves down to asking whether a normal curve will reasonably *graduate* the material and find it does, are we to follow it up by asserting that either sample or parent-population follows a normal distribution? I should say: Certainly *not*. I have never found a normal curve fit anything if there are enough observations! The astronomical data provided to prove that errors of observation follow normal curves are pitiably scanty, and if proper tests are applied usually show that they do not! The fact is that all these descriptions by mathematical curves in no case represent 'natural laws'. They have nothing in this sense to do with 'hypothesis' or 'reverse of hypothesis'. They are merely *graduation curves*, mathematical constructs to describe more or less accurately what we have observed.

(vii) The reader will ask: "But if they do not represent laws of Nature, what is the value of graduation curves?" He might as well ask what is the value of scientific investigation! A good graduation curve—that is, one with an acceptable probability—is the only form of 'natural law', which the scientific worker, be he astronomer, physicist or statistician, can construct. Nothing prevents its being replaced by a better graduation; and ever bettering graduation is the history of science.

What is the use of good graduation curves? Ask the actuary! Such curves enable a mass of details to be summed up with reasonable probability in the knowledge of a few constants, and from those constants we obtain new knowledge of the properties of the mass. Take only the importance of a life table graduated by the Makeham-Gompertz curve and consider, what new knowledge flows from it. But

after all, it is only a graduation curve and it is open to anyone to find a better one! If Continental statisticians in the bulk do indeed hold the views of Mr. Buchanan-Wollaston, it can only be that they have not really studied and grasped the fundamental literature of the subject.

Blood Group Inheritance

SEVERAL theories of the inheritance of human blood groups have been proposed, but none has been completely satisfactory.

(i) The theory of two independent pairs of Mendelian factors, proposed by Hirschfeld and von Dungern[1], leads to the equilibrium condition

$$ps = qr$$

where p, q, r, s are the frequencies of the groups AB, A, B, O. But[2,5] in all observations of the distribution of the groups,

$$ps < qr.$$

(ii) The corresponding condition arising from Bernstein's multiple allelomorph theory[3,5] is

$$\sqrt{q+s} + \sqrt{r+s} = \sqrt{s} + \sqrt{p+q+r+s}.$$

This is satisfied with sufficient accuracy in all observed distributions, but this theory fails to account for the observed occurrence of a small percentage of groups AB and O in the offspring of $AB \times O$ matings.

(iii) Bauer[4] proposed to account for this by the mechanism of 'crossing-over'. His theory is the subject of criticisms in a paper now in course of preparation, in which we shall show that the following theory, which is not exactly what Bauer stated, is the one to which his premises should have led:

(iv) The blood groups are inherited in association with two linked pairs of Mendelian factors, A, a, B, b. There are thus four kinds of gametes,

$$AB,\ Ab,\ aB,\ ab;$$

and ten genotypes:

$AB.AB$, $AB.Ab$, $AB.aB$, $AB.ab$, $Ab.aB$—phenotypically group AB;
$Ab.Ab$, $Ab.ab$—group A;
$aB.aB$, $aB.ab$—group B;
$ab.ab$—group O.

If crossing-over takes place, we may suppose that there is a certain probability ω that the genotype $AB.ab$ transmits the gametes Ab and aB normally transmitted by the genotype $Ab.aB$; and the same probability of vice versa.

In Bauer's theory (iii), ω is about 0·055. If $\omega = 0$ and the first four genotypes in the above scheme are initially (and therefore permanently) absent from the population, the theory (iv) reduces to (ii). With $\omega = \frac{1}{2}$, (iv) is indistinguishable from (i).

The theory we actually propose is (iv) with $\omega = 0$. (This also gives results indistinguishable from (i) in all matings which do not involve the distinction between the genotypes $AB.ab$ and $Ab.aB$.) It is unnecessary to postulate crossing-over, since with this theory $AB \times O$ matings would anyhow give rise to some AB and O offspring. But, further, crossing-over is definitely precluded, since it may be shown to lead to the same equilibrium condition as the theory (i). There is no corresponding condition when $\omega = 0$; that is to say, any distribution of the groups can be in stable equilibrium provided that the genotypes are suitably distributed. But for equilibrium distributions in which AB is rare compared with the other groups, the theory approximately coincides with (ii); and therefore, as in that theory,

$$\sqrt{q+s} + \sqrt{r+s} = \sqrt{s} + \sqrt{p+q+r+s}$$

approximately. This, as already pointed out, agrees with observation, and therefore (since p is generally about 5 per cent) corroborates the new theory.

The rare recorded occurrences[5] of A offspring from $O \times O$ matings, of AB and B from $A \times O$, and of AB and A from $B \times O$, cannot be accounted for genetically by any of these theories. They must still be put down to mistaken parentage or faulty technique in group determination.

Thus the theory proposed has all the advantages of its predecessors, with fewer disadvantages.

Technique of Factor Analysis

FACTOR analysis is a subject upon which Prof. G. H. Thomson, Dr. Wm. Brown and others have frequently written letters to NATURE. This analysis is concerned with a selected population of n individuals each of whom has been measured in m tests. The (m) $(m-1)/2$ intercorrelations for these m variables are subjected to either a Spearman or other factor analysis.

The technique, however, can also be inverted. We begin with a population of n different tests (or essays, pictures, traits or other measurable material), each of which is measured or scaled by m individuals. The (m) $(m-1)/2$ intercorrelations are then factorised in the usual way.

This inversion has interesting practical applications. It brings the factor technique from group and field work into the laboratory, and reaches into spheres of work hitherto untouched or not amenable to factorisation. It is especially valuable in experimental aesthetics and in educational psychology, no less than in pure psychology.

It allows a completely new series of studies to be made on the Spearman 'central intellective factor' (g), and also allows tests to be made of the Two Factor Theorem under greatly improved experimental conditions. Data on these and other points are to be published in due course in the *British Journal of Psychology*.

Rainfall-Evaporation Ratio in Relation to Locust and Grasshopper Outbreaks

A WIDESPREAD outbreak of the migrating grasshopper, *Chortoicetes terminifera*, Walk., occurred in Australia during 1933–35. Reports show that, in South Australia, small, local swarms appeared during the summer 1932–33 in certain districts in the pastoral country about 150 miles north of the 10 in. annual isohyet (see Fig. 1). During 1933–34 swarms were widely distributed and in some areas extended about 100 miles south of this rainfall line. During 1934–35 they became generally distributed southwards over the agricultural areas of the State.

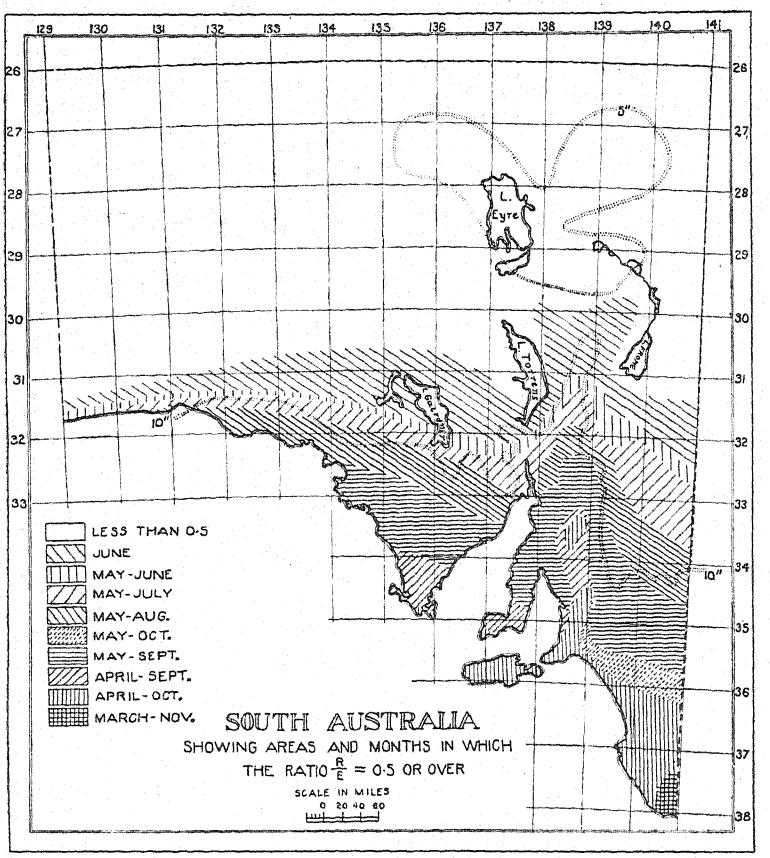

FIG. 1.

These widespread invasions develop only at irregular intervals of several years; the presence of the insects in numbers, in the southern areas of the State, is temporary. Restricted outbreaks occur more frequently in certain areas situated immediately north of the 10 in. isohyet; in some instances the swarms may extend southwards into the wheat belt.

Local grasshopper swarms appear from time to time during the summer months in the pastoral country north of the 10 in. isohyet; their appearance is associated with summer rains. The endemic centres of *Ch. terminifera* appear to be in this region but they have not yet been defined. The average annual rainfall over this portion of the State is about 5–10 in. (see Fig. 1); there are wide fluctuations about the mean from year to year, resulting in prolonged periods of drought; much of the rain falls during the summer months. The southern portion of the State includes the better rainfall agricultural areas. Precipitation is more reliable and most of the rain falls during the winter period (May–October), the summer being hot and dry.

Ch. terminifera lays its eggs in particular soils to a depth of about 2 in. Dryness of the soil results in an enforced diapause in the egg stage, but experimental data are not yet available for this species: Faure[1] showed with *Locustana pardalina*, Walk., in South Africa, that the eggs remained viable in dry soil for 37 months. Soil moisture is determined primarily by rainfall in relation to evaporation (R/E). I have already shown how mean monthly values for the ratio R/E may be computed for Australia[2]. In the accompanying map of South Australia (Fig. 1), the months and approximate areas are shown in which the mean monthly values for R/E are 0·5 or more. It is considered tentatively that these values, in South Australia, give adequate soil moisture for the development of the eggs of *Ch. terminifera* provided temperature is suitable. It may be noted that, in countries where data for evaporation are not available, the ratio of precipitation to atmospheric saturation deficit may be used as an index of aridity; this ratio was originally employed by Meyer in 1926 (vide Prescott[3], 1934).

The mean monthly temperature for the coldest month (July) over the greater part of South Australia does not fall below 50° F.; over the elevated districts of the agricultural areas, it varies between 45° and 50° F. The temperature value for the developmental zero of the eggs of *Ch. terminifera* has not yet been determined. It is evident, however, that in South Australia temperatures will not be below this value for long periods. Eggs laid in summer, in the southern portion of the State, will hatch in autumn or early winter, particularly if the wet season opens early; this period is unfavourable for the insects, and mortality is heavy; this was the case in the autumn of 1935. When the wet season opens late, the insects hatch out nearer to the spring months, particularly in the northern hatched areas shown on the map; this was the case in 1934, and the survival rate of the insects in the spring was high. The favourableness of the conditions will vary according to the character of the wet season. In the northern pastoral areas monsoonal rains in the summer months may cause creeks and flats to be temporarily flooded; adequate moisture will be available for a time, for development of the eggs and growth of ephemeral grasses for the insects. Apart from weather factors, soil type and vegetation are important in relation to the distribution of the endemic centres of *Ch. terminifera*.

It would appear, therefore, that temporary invasions of the southern portion of South Australia by *Ch. terminifera* are closely correlated with the rainfall of particular seasons. The extent of the invasion

depends largely upon the duration of a combination of favourable conditions in the endemic areas and in the southern portions of the State. A detailed study of the ecology of the species is in progress.

Wood Hemicelluloses

SINCE the isolation of 'starch' from wood[1] another product has been obtained from the cell walls of oak sapwood which, instead of giving the usual blue colour with iodine, gives a royal purple colour reverting to blue on standing. This latter substance is more closely allied to hemicellulose A[2] than the starch of the cell contents since it appears to be made up of:

Uronic and aldobionic anhydride residues (14 per cent approx.)
in addition to—
Anhydro-xylose .. .. (10 per cent approx.)
and
Anhydro-glucose residues .. (75 per cent approx.)

Attempts are now being made to prepare starch from oak leaves in quantities sufficient for analysis. A small sample already obtained has yielded on hydrolysis with 12 per cent hydrochloric acid an amount of carbon dioxide corresponding to 24·4 per cent of uronic anhydride. These results appear to permit of the formulation of the hypothesis that certain of the hemicelluloses of oak wood are derived from starch in a series of steps involving the oxidation of primary alcoholic groups and the subsequent formation of anhydro-xylose residues by decarboxylation. If the hypothesis is correct, the term 'hemicellulose' can no longer be applied to the acid polysaccharides in question, and the alternative general term 'amylo-uronides' is therefore suggested. If the furfuraldehyde-yielding complexes associated with the cellulose of wood are derived therefrom by a similar series of reactions, the term 'hemicellulose' might still be reserved for them.

Amorphous Antimony

IN a previous letter[1], I showed that a thin layer of antimony produced by distillation in a high vacuum is amorphous. This conclusion was drawn from the fact that the electron diffraction pattern consisted of broad bands always showing exactly the same appearance (width, intensity, etc.); this could scarcely be understood if the state were only colloidal. The following researches corroborate and extend this view:

When such an amorphous layer is heated to 120°–150° C. (the thinner layers requiring the higher temperatures), the diffraction pattern changes into the ordinary powder diagram of antimony, consisting of a large number of sharp rings. If the original layer was *very* thin, the rings after heating remain more or less broad as a consequence of the small size of the crystallites; the difference from the original amorphous pattern is, however, unmistakable even in this case. In all cases the crystallites produced by heating are oriented at random, differing in this respect from those formed by spontaneous crystallisation at room temperature, described previously.

These results throw a new light on the so-called 'explosive' state of antimony, discovered by Gore almost a century ago. As is well known, this state is obtained by electrodeposition; in this case there is no upper limit to the thickness of the deposit obtainable. The diffraction patterns of such layers[2] proved to be identical with those of amorphous antimony described above. *This shows that Gore's explosive antimony is essentially identical with our pure amorphous antimony.* Explosive antimony is known, however, to include some 10 per cent of the salt electrolysed; this may be present as thin films (probably monomolecular) surrounding small quantities of pure amorphous metal, thereby inhibiting their crystallisation.

From this picture, it may be expected, for example, that the electric resistance of explosive antimony will not be determined by the metallic parts but mainly by the salt films[3]. Experimentally, I have found values for the resistivity about 100 times that of ordinary antimony, and other observers[4] even give a factor 1000. These high values, as well as their irreproducibility, are arguments in favour of the view put forward above. Other properties, however, might be less sensitive to the presence and quantity of inclusions, and should then be the same as for pure amorphous antimony. As such we shall here consider the heat of crystallisation and the diamagnetic susceptibility:

It is well known that explosive antimony derives its name from the fact that it may change more or less explosively into ordinary antimony, or, as we may now say, it crystallises more or less explosively. This 'explosion' may be caused by scratching or by heating to about $97° \pm 2°$ C. Now the heat of crystallisation liberated in this process, measured by E. Cohen and Th. Strengers[5], is found to be 20 cal./gm. This is of the same order of magnitude[6] as the heat of crystallisation from the liquid at the melting point (24 cal./gm.). I have measured the diamagnetic susceptibility of explosive antimony and find that it increases markedly when the transition to ordinary antimony is brought about. This is again in agreement with the change in diamagnetic susceptibility at the melting point. *The two results together strongly suggest that the explosive (amorphous) state of antimony is the supercooled liquid state.*

The experiments were made in collaboration with Mr. P. Teunissen in the laboratory of Prof. D. Coster. The full paper is to appear in *Physica*.

Raman Effect in Solutions of some Amino Acids

THE purpose of this letter is to report some measurements of Raman frequencies in solutions of glycine, alanine, tyrosine and cystine, which have been observed as a preliminary to the development of a spectroscopic method of analysis for molecules of this class.

An air-cooled quartz-capillary mercury arc furnished the exciting light, filter solutions of sodium nitrite and praseodymium ammonium nitrate permitting excitation by the 4358 A. line. The spectrograph was a two-prism glass instrument having a dispersion of 23 A./mm. at 4500 A.

Solutions (in water) of samples of glycine and alanine which had been recrystallised several times to remove impurities exhibited some fluorescence; this, however, decreased upon still further recrystallising. Introduction of a small amount of potassium iodide to these solutions quenched the fluorescence very effectively.

The observed Raman frequencies (in cm.$^{-1}$) together with visual estimates of the relative intensities are as follow:

Glycine (15 per cent solution in water, 10 per cent KI):—506 (3), 899 (8), 1036 (4), 1112 (2), 1332 (8), 1411 (10), 1445 (4);

Alanine (15 per cent in water, 8 per cent KI):—528 (2), 851 (6), 1305 (4), 1358 (5), 1383 (1), 1417 (10), 1466 (6), 1715 (4);

Tyrosine (5 per cent in 0·9 *N* HCl):—646 (3), 844 (9), 1216 (6), 1359 (4), 1448 (1), 1620 (10);

Cystine (8·33 per cent in 1·1 *N* HCl):—503 (10), 670 (10), 1633 (3), 1736 (3).

These lists are not to be regarded as complete for the spectral region covered, as weaker lines have been no doubt obscured by scattered continuous radiation from the mercury arc. The range of error of the measurements is roughly ± 3 cm.$^{-1}$.

To test the effect of varying the concentration, three solutions of glycine having concentrations of 7·5, 15 and 22·5 per cent were examined. The Raman lines showed no shift in position greater than 2 cm.$^{-1}$. Varying the amount of potassium iodide in these solutions from zero to 40 per cent also produced no shift greater than the error of measurement.

Initiation of the High-Frequency Discharge

WHEN the gas hydrogen in a wide tube is excited by means of a high-frequency alternating potential $V\sin 2\pi nt$, applied between two parallel plate electrodes, the relation between the sparking potential $V_s\sin 2\pi nt$, the gas pressure p, and the inter-electrode distance d for values of pd in excess of the critical value is of the simple form $V_s = A + Bpd$, where B is a gas constant and A depends upon the frequency n and the electrode surfaces[1].

This form of Paschen's law is consistent with the hypothesis that the peak potential V_s just before the initiation of the discharge is made up of two parts, (1) an electrode fall V_E and (2) a uniform field in the gas Bp. At pressures considerably in excess of the critical value, it may be assumed that V_E occurs in a very small fraction of the distance d. Then V_E will be approximately equal to A.

In the accompanying diagram (Fig. 1) an experimental curve is shown which exhibits the variation of V_s with p in a tube the electrodes of which were of copper, 8 cm. in diameter and 2·58 cm. apart. The frequency of the applied potential was $2{\cdot}03 \times 10^7$ c.p.s. This curve is typical of those which have been determined for frequencies between 8×10^6 c.p.s. and 9×10^7 c.p.s. It can be explained in terms of (1) ionisation by positive ions at the cathode and (2) ionisation by electronic impact in the gas. The former is connected with the electrode fall (72 volts) and the latter with the gradient $B = 21{\cdot}6$ volts/cm./mm. of mercury.

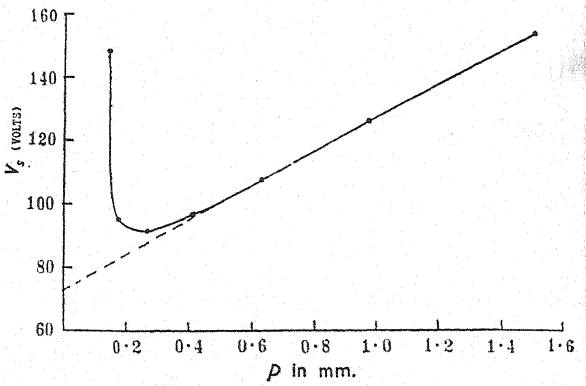

FIG. 1.

If it is assumed that a typical free electron moves under the action of the electric field so that $m\ddot{x} = E\epsilon\cos(2\pi nt - \varphi)$ and that a discharge occurs when the electron gains its ionising velocity at a given distance $L = K/p$ from its starting point, it can be shown that the mode of variation of E with p for a discharge is,

$$E = \frac{\pi n \sqrt{\frac{2V_0}{e/m}}}{\sin \frac{2\pi nK}{p\sqrt{(2V_0 e/m)}}}. \quad . \quad . \quad . \quad . \quad (1)$$

For large values of p, $E = V_0 p/K$, giving the constant gradient $B = V_0/K$.

When various experimental curves are examined by these hypotheses, the following facts emerge:

(*a*) The ionisation potential V_0 of the gas is correctly predicted.

(*b*) The value of K is much larger than that deduced from the kinetic theory on the assumption that L is the electronic mean free path.

(*c*) In discharges at *all* high frequencies, the critical pressure p_c is such that $d = K/p_c$ where K is calculated from the gradient V_0/K.

This last fact indicates that the minimum E predicted by equation (1) is not in general observed. Owing to the relatively large electrode fall, the equation only holds at the minimum for certain frequencies or for tubes in which d is very large. Fig. 1 is drawn for a value of n for which the theory of equation (1) holds very exactly down to the critical pressure.

A detailed account of the experiments which have led to these conclusions, and of others relating to the initiation of discharges by means of constant potentials, will be published elsewhere in due course.

JOHN THOMSON.

The University, Glasgow.
July 1.

[1] J. Thomson, *Phil. Mag.*, **18**, 696; 1934. The value given for B in this paper is in error, due to a mistake in the estimate of a capacity. The correct value for the experiments there described is 26 volts/cm./mm.

Multiplanar Cyclohexane Rings

IN 1931 I published a paper in the *Journal of the Indian Chemical Society* in which the four isomeric modifications of 4-methyl cyclohexane-1-carboxy-1-acetic acid were described[1]. In a recent publication S. Goldschmidt and G. Grafinger[2] observed that they could not isolate the acid *B*, as described above, and consequently they concluded that actually 4-methyl cyclohexane-1-carboxy-1-acetic acid existed in only two modifications, one melting at 137° and the other at 174°. It appeared to me rather strange that the work, which was repeated a number of times before publication, should be altogether wrong. It was, therefore, considered desirable to get the work repeated once more in my presence, and this has accordingly been done now by a student of mine, Mr. Asutosh Mukherji, with the result that we found no difficulty whatever in isolating all the four modifications of the acid as described before. It may, however, be recorded here that the solubility of the ammonium salt of the acids *A*, *B* and *C* in absolute alcohol is as follows :

One gm. of acid *A* dissolves in 75 c.c. of boiling absolute alcohol.
" " " *B* " " 45 " " " " "
" " " *C* " " 34 " " " " "

The quantity of the absolute alcohol must, therefore, be carefully regulated, otherwise, if acids *B* and *C* come out together in alcoholic solution, it becomes very difficult to separate them from one another. Regarding the suggestion of Goldschmidt that the acid *B* may be a eutectic mixture of acids *A* and *C*, it appears to be untenable and not based on experimental evidence. The mixture of the acids *A* and *C* gave at no time any sharply melting substance which would melt at 129° or near about it as the acid *B* does. The same is true for the acid *D* also. It is difficult to say whether it is the unsuitable method of separation adopted by the German chemists that is responsible for their failure to get the acid *B* and *D*. It may incidentally be mentioned that these isomers are not at all similar to any of those isolated from the *para* or *ortho* methyl cyclohexanone. Although all the expected isomeric acids from these latter ketones have not yet been isolated, the work so far completed will be published very shortly elsewhere.

The *p*-methyl cyclohexanone and other ketones of the series are now being prepared with different catalysts in order to see if the quality of the ketones has anything to do with the formation of the isomeric acids.

Vapour Pressure of Hexadeuterobenzene

IT has recently been recorded[1] that the vapour pressure of deuterium iodide is slightly, but definitely, greater than that of protium iodide, a behaviour qualitatively analogous to that exhibited by the two hydrogen fluorides[2]. This type of anomaly is, therefore, not confined to substances which are generally recognised as associated in the vapour state[3].

We know an even clearer example : the vapour pressure of C_6D_6 is greater than that of C_6H_6 for the whole temperature range 0°–80° C. (below the freezing point, 6·8°, the liquid is supercooled) over which we have measured it. The boiling point of C_6D_6 at normal pressure is 0·8° lower than that of C_6H_6, contrary to a recent claim that the former is higher[4].

Inverse Probability

IN my letter[1] of May 4, I was not defending Eddington's solution of his problem in inverse probability, but was attacking Dr. Dingle's discussion[2] of his own simplified problem : If *A* and *D* each speak the truth once in three times independently, and *A* says that *D* lies, what is the probability that *D* speaks the truth ? In his discussion Dr. Dingle said, "Sir Arthur's treatment effectively combines the knowledge of *D*'s moral character with that of *A*'s. But is it not clear that such combination is purely fictitious ? From our knowledge of *D* the probability is $\frac{1}{3}$; from our (independent) knowledge of *A* it is $\frac{2}{3}$. The results are inconsistent because the data are independent ; we are effectively defining probability in different ways". It should be clear from my solution of Dr. Dingle's problem that the answer is neither $\frac{1}{3}$ nor $\frac{2}{3}$, but $\frac{1}{2}$, and nothing else. There are really no inconsistencies, as I showed by drawing up the association table.

I do not agree with Dr. Dingle's more recent[1] assertion, that one must ". . . either (*a*) define probability in a purely mathematical way and so obtain a unique solution which may be both consistent and correct . . . , or (*b*) refrain from calling meaningless mathematical functions 'probability', and then obtain two solutions to each problem". My treatment used "probability" in the simplest and perhaps most significant meaning of the word. Out of $4N/9$ cases where *A* says that *D* lies, *D* actually lies $2N/9$ times and tells the truth $2N/9$ times. Does Dr. Dingle seriously maintain that the ratio, $2N/9 \div 4N/9 = \frac{1}{2}$, is a "meaningless mathematical function", or that, given that our case is one of these $4N/9$ cases, there is any lack of significance in saying that the probability that *D* tells the truth is $\frac{1}{2}$?

Although I cannot subscribe to Dr. Dingle's arguments, I am inclined to agree with him that Eddington's solution was incorrect. The data supplied by Eddington do not seem to me to be sufficient to allow one to write down the class frequencies in a contingency table.

T. E. STERNE.

Cambridge, Mass.
July 11.

[1] NATURE, **135**, 1073; 1935.
[2] NATURE, **135**, 451; 1935.

THE point at issue between Dr. Sterne and myself is ultimately whether consistency is equivalent to significance or not. Evidently it is not easy to clear it up in a few sentences, and the Editor has invited me to write an article on the whole question of probability which will appear in NATURE shortly.

I will only say here that in the passage which Dr. Sterne quotes from my review, I called the results "inconsistent" because they were ostensibly different values for the same thing—"probability". I thought it would be understood that if those two things were called by different names, and made no pretensions to be the same thing, there would be no inconsistency. In other words, I did not attribute inherent inconsistency to the problem but to two possible ways of defining the solution.

Constitution of the Prosthetic Group of Catalase

KARL ZEILE[1] in 1930 was the first to provide evidence that the catalytic activity towards hydrogen peroxide of purified preparations obtained from liver and from marrow seedlings is intimately connected with a pigment exhibiting the spectral behaviour of a complex consisting of a hæmatin group—the iron being stabilised in the trivalent state—and of a colloidal component. The position of the absorption bands of the pyridine hæmochromogen and of the porphyrin, obtained in solution by treatment with hydrazine and acetic acid, led him to conclude that the hæmatin contained in the enzyme complex was either identical with, or was an isomer of, the prosthetic group of natural hæmoglobin.

Solutions rich in catalase were obtained by a method embodying fractional alcohol precipitation, removal of hæmoglobin by chloroform denaturation, adsorption of the enzyme on alumina gel, elutriation with secondary sodium phosphate, and concentration by acetone-CO_2-treatment in the cold. The active hæmatin-protein complex was split by acid acetone, the hæmin precipitated by evaporating the acetone, and recrystallised from propionic acid and HCl in order to remove admixed biliverdin crystals. About nine milligrams of a pure hæmin were obtained from the catalase prepared from fifty pounds of horse liver. The spectroscopic properties and the enzymatic activities of the various fractions were determined throughout.

The hæmin, when acted upon by hydriodic acid and glacial acetic acid, yielded a porphyrin the spectrum of which was identical with that of a sample of pure mesoporphyrin IX kindly given to me by Prof. Otto Warburg. The dimethyl ester obtained by treatment with HCl in methyl alcohol shows the same spectrum as does mesoporphyrin-IX-dimethyl ester. Final proof of the identity is afforded by the fact that the compound (m.p. 214°, uncorr.), when added to an equal amount of synthetic mesoporphyrin-IX-dimethyl ester (m.p. 212°, uncorr.) caused no depression of the melting point of the latter (mixed melting point 213°, uncorr.). I am indebted to Prof. Hans Fischer for a sample of the synthetic ester.

The conclusion seems, therefore, to be justified that the hæmatin group of catalase is a derivative of ætioporphyrin III and possesses a porphin skeleton with the same arrangement of the side chains as is found in the natural blood pigment, that is, in protohæmatin IX.

It is, perhaps, of interest to note that according to D. Keilin and R. Hill[2] and to K. Zeile and F. Reuter[3], the component *c* of cytochrome is also a derivative of ætioporphyrin III.

The details of this investigation will be published elsewhere.

The high activity of catalase is obviously due to the union of the hæmatin with a special protein[4]. Work on the nature of this protein is being continued.

Colour of the Positive After-Image of a Colour

IN certain conditions, the colour of the positive after-image of any colour or white is purple. It is best to use only one eye and to have both eyes covered with a black cushion before performing the experiment. The object should then be viewed for the shortest possible time and the black cushion be replaced over the eye. If tried with a spectrum, the whole of the after-image becomes purple.

If on a piece of white cardboard eighteen inches square a series of small squares of red and blue cardboard, each about three quarters of an inch square, be pasted to cover a surface of about nine inches square, and the whole is placed in sunlight and viewed as previously mentioned at a distance of about three feet, a brilliant positive after-image, red, blue and white, will be seen for a fraction of a second. Then all changes to purple, which becomes brighter and then disappears from without inwards in about eight to twelve seconds without becoming negative; the last thing to be seen is a whirlpool movement in the centre of the field of vision.

With spectral colours projected on a screen in a dark room the positive after-image of all becomes purple and disappears without changing to negative when viewed for the shortest possible time. When the eye is moved, the after-image spreads out, a portion of the retina not previously stimulated being affected.

These facts suggest very strongly that the photochemical stimulus in vision is liquid and movable in the retina.

Dental Caries in Prehistoric South Africans

THE Matjies River Shelter[1] has yielded a very large number of skulls with hundreds of teeth. The deposit commences with a form of the Mossel Bay culture (which may be called Early Mossel Bay) which, in natural superficial strata of the neighbourhood, and in a shelter about eight miles away at Plettenberg Bay, follows immediately on the last phase of the Stellenbosch culture. This phase of the Stellenbosch can be found from Plettenberg Bay to Mossel Bay in a hard red sand lying immediately below the surface layer of black sand, and may therefore be accepted as the end of the Pleistocene; the whole of the deposits of the Matjies River Shelter must therefore be taken to be Holocene.

My collection contains: teeth of one burial from

the late Stellenbosch of Plettenberg; teeth of two adult and one baby burials from the Early Mossel Bay of Matjies River Shelter; teeth from one burial of the same layer, Plettenberg Bay; teeth from about fifteen burials, with cremated heads, near the top of the Mossel Bay layer; teeth from more than a dozen adult burials in the Wilton-without-pottery layer. *In not one of this large collection of teeth is there the slightest sign of dental caries.*

After this the deposit changes completely; it now consists almost wholly of shells (largely *Mytilus*) instead of ashes; and, from now onwards, caries is very common.

The indication from this area therefore bears out the experience of European anthropologists—that caries is a comparatively modern disease and that no skull showing this condition can be regarded as ancient. Will anthropologists, in view of these facts, revise their views on certain South African finds—I may be allowed to mention particularly the Broken Hill and the Springbok Flats skulls?

Nomenclature of Corpus Luteum Hormone

DURING the past year, the progestational hormone has been isolated from the corpus luteum in pure form and its constitution established. Heretofore, two different names have been used in the literature for this hormone (progestin, luteosterone). For the sake of international uniformity, we agree to use hereafter in the scientific literature only the name *progesterone* for the pure hormone. As is known, the pure hormone exists in two different forms, one melting at 128° (uncorr.) and the other at 121° (uncorr.). The higher melting form (Compound B of Wintersteiner and Allen[1] and Compound C of Slotta, Ruschig and Fels[2]) will be known as α-progesterone, and the lower melting form (Compound C of Wintersteiner and Allen and Compound D of Slotta, Ruschig and Fels) as β-progesterone. We hope that these names will be generally accepted in the scientific literature.

Points from Foregoing Letters

In reply to Mr. Buchanan-Wollaston's criticism of British statistical methods, Prof. Karl Pearson enumerates some of the uses of the P, χ^2 test, which was devised to find whether a given curve used in graduating observations was a good 'fit'.

When blood from two individuals is mixed, clumping of the red corpuscles may occur, a fact of great importance in blood transfusion. Human beings have been classified into four groups *A*, *B*, *AB*, and *O*, according to their behaviour when mixed. Dr. J. F. Edwards and Dr. I. M. H. Etherington propose a new theory of blood group inheritance, depending on two linked pairs of Mendelian factors, the hypothesis of 'crossing-over' being discarded.

Dr. J. Davidson gives a chart showing the rainfall-distribution ratio in South Australia in relation to the recent outbreak of the migrating grasshopper, *Chortoicetes terminifera*, showing the necessary soil moisture needed for the development of eggs of that insect.

Further investigations to determine the steps by which the hemicellulose constituents of the wood of the oak are formed from starch are reported by W. G. Campbell.

X-ray investigations show that the electrolytically deposited 'explosive antimony', so-called because it crystallises more or less explosively when scratched or heated, is identical with the amorphous films of antimony produced by distillation in a high vacuum. Dr. J. A. Prins suggests that they represent a super-cooled liquid state.

As a step towards the spectroscopic analysis of amino-acids, Norman Wright and W. C. Lee have determined the Raman spectra of the light scattered by solutions of glycine, alanine, tyrosine and cystine.

Dr. J. Thomson discusses the mechanism of the initiation of the high-frequency glow discharge in hydrogen. From the results of his experiments, he concludes that there is space-charge present before the discharge begins and that this produces a non-uniform electric field. The experiments are consistent with a simple theory of ionisation by electronic impact. The ionisation potential of the gas may, in certain circumstances, be deduced from the results.

The observation is made by Dr. C. L. Wilson that as the boiling point of hexadeuterobenzene is lower than that of ordinary benzene, benzene behaves in a manner analogous to hydrogen fluoride, hydrogen iodide and acetic acid.

Dr. Dingle admitted that Dr. Sterne had obtained a unique solution of an apparently inconsistent problem of Dr. Dingle's, in inverse probability; but contended that Dr. Sterne's combination of the data had nothing to do with probability. Dr. Sterne disagrees with this contention, claiming that he uses "probability" only in a simple, usual and significant meaning of the word. Dr. Dingle still holds to his position, which he promises to maintain in a forthcoming article.

The non-protein radical of the enzyme catalase (found in liver and in most living tissues) has been isolated by Dr. Kurt G. Stern, who shows that it is derived from ætioporphyrin III; this is also the case with the component *c* of cytochrome, a cell-pigment, originally found in muscle, which plays an important part in the utilisation of oxygen by living tissues.

ERRATUM. The approximate velocity of slow neutrons as indicated by the experiments of Dr. O. R. Frisch and E. T. Sørensen, mentioned in this column in NATURE of August 17, should have been 2,000 metres per second instead of 200.

Research Items

Archæological Research and Peat Deposits in East Anglia

In the report on the recent excavations at Peacock's Farm, Shippea Hill, Cambridgeshire, on behalf of the Fenland Research Committee, by Mr. J. G. D. Clark, Dr. H. and Mrs. M. E. Godwin and Mr. M. H. Clifford (*Antiquaries J.*, **15**, 3), reference is made to the employment of two distinct, but complementary, methods of peat analysis as an aid to the work of the archæologist. Of these the first, pollen analysis, is by now familiar. The second, that of examining all other plant remains in the peat beside pollen, has been carried out at Peacock's Farm by Mr. M. H. Clifford. At present it is regarded as only in an early stage, but promising useful development. It has the great advantage that it is an index of the vegetation actually growing on the site in a way impossible for pollen analysis only. In the present instance, in the lower peat below forty-eight inches, all the wood present consists of alder roots, though the pollen analysis shows that the alder was not present at this level. Pine wood is absent, though pine pollen is present and strikingly dominant. In the black layer of the microlithic horizon the plant remains are unidentifiable, except for alder rootlets and a few fruits of hemp agrimony. At 30 inches, a striking change occurs. Wood is very abundant, and there are leaves and fruits of many trees and bushes. At 32 inches, stem wood of alder occurs for the first time, supplemented at 28 inches by stem wood of ash and hazel, at 14 inches by *Rhamnus catharticus* and at 4–6 inches by elm-wood. To these must be added fruits of *Rhamnus catharticus*, dogwood, hazel, raspberry and leaves of oak. This assemblage suggests dense bush and tree growth corresponding to the later stages of 'carr' development in present-day vegetation. From 16 inches to the top of the upper peat there are signs of a return to aquatic conditions, first in the fruits of hemp agrimony and prickly sedge, and afterwards in the rhizomes of reed-mace. There is no evidence of a break in the peat formation due to land uplift or other cause.

Conventionalisation of Design in the Solomon Islands

The simplification and modification, including elaboration in geometric form, of a naturalistic design in the Solomon Islands has been analysed by Capt. T. A. Joyce (*Man*, **108**, July) in relation to a peculiar element, which constitutes a constant feature in the turtleshell network of head ornaments. These are worn as forehead ornaments by the people, and consist of a white shell disc overlaid with a 'fret-work' of turtleshell. The delicate fretted patterns bear witness to a remarkable degree of technical skill on the part of a people who had no sharper tool than a shark's tooth. Since the ornaments are circular, the design is radial, and an almost consistent element is a series of spokes, with what may be termed an 'elbow' in the centre of each, the cutting of which must have been a matter of considerable difficulty. It seems likely, therefore, that this feature must have a definite meaning. A clue is afforded by the hollow wooden figures of a bonito fish in which the skull and jawbones of a dead man are enclosed after the great funeral feast has been held. In an example of such a bonito fish now in the British Museum, the back fin of the bonito is its most prominent figure; and the bonito itself is important in Melanesia as a clan-badge. The analysis of the development of the bonito fin can be followed further in the design of a bamboo lime box, also in the British Museum, in which the fish appear reduced to their lowest dimensions; but in all of them there is a highly developed back fin. In these the design is a white fish on a shaded ground; but if the design is reversed to become a shaded design on a white ground, we get the *motif* provided by the radial bars with elbows of the head ornaments. The design on the lime box, therefore, appears to explain that of the head ornaments and to afford another example of the tendency of life forms, simplified and repeated, to become geometrical.

Evolution of the Skull in Horses

The evolution of the skull in the Equidae is the subject of two papers by Dr. R. Cumming Robb (*J. Genetics*, vol. 31, No. 1). By measurements of the skulls of various fossil and living horses, he shows that increase in size from the Eocene *Hyracotherium*, weighing perhaps 20 lb., to the modern Percheron weighing more than 2,300 lb., is accompanied by progressive increase in the pre-ocular length. In titanothere evolution, on the contrary, the preponderance of increase has been in the post-ocular region. This continuous evolution in the shape of the horse skull is a concomitant of one hundred-fold increase in the weight of the animal. If the animal is as small as *Hyracotherium*, the facial index (face length/cranium length) is about 0·8. *Merychippus* and a Shetland pony are of larger but similar size, and have a facial index about 1·5. The law of relative growth will thus account for continuous change in the proportions of the skull, but size mutations may be required to explain the progressive increase in the size of the animal. By measurements of fœtal and post-natal stages in the development of the horse, Dr. Robb shows the same progressive preponderance of the face, with the same linear relationship between muzzle length and skull length. The 'orthogenetic' trend in the evolution of the skull is therefore regarded as a direct result of the increasing size of the animal. Whether this evolutionary increase in size, which is characteristic of so many animal groups, has been aided by natural selection, and whether it has been determined by mutations in size genes, remains undetermined.

The Gorgonid Family, Plexauridæ

In a series of three recent publications, Dr. G. Stiasny has made notable contributions to our knowledge of the Gorgonaceæ. The major of these (*Siboga*-Expeditie, Monographie XIII*b*^{7}. Leyden: E. J. Brill, 1935) is a revision of the Plexauridæ based not only on the *Siboga* material, Nutting's original account of the *Siboga* Plexauridæ being insufficient, but also on other material in the possession of the Rijksmuseum van Natuurlijke Historie at Leyden, including two collections made by Prof. H. Boschma at the Tortugas and Bermuda in 1925. Seven new

species and two new varieties are described, while one species receives a new name. There are many new records of distribution of both Indo-Pacific and Atlantic species. Dr. Stiasny, following Prof. S. Hickson in this, deplores the lack of experimental data on the effect of environment on the form of Gorgonids. It is indeed more than time that systematists were not only able but also actually encouraged to study their material, where possible, in the living condition. This necessity is borne out by the second of these communications (*Zool. Anz.*, 110, 179–190; 1935) in which Dr. Stiasny redescribes *Briareum arbestinum*, Pall., the most abundant, and among the most thoroughly studied, of all West Indian Gorgonids. He was able to do this owing to the beautiful preservation of material collected by Prof. Boschma at the Tortugas. The polyps are much larger than previously described and the canal system different. The third paper (*Zool. Anz.*, 109, 236–245; 1935) contains a short summary of the diagnostic features of the known species of the family Plexauridæ.

Nerve Plexuses in *Amphioxus*

DR. J. BOEKE describes (*Quart. J. Micr. Sci.*, 77, Pt. IV; 1935) a nerve plexus on the wall of the liver and adjoining parts of the intestine of *Amphioxus*, with numerous stellate ganglion cells, which may be compared with the plexus of Auerbach of the higher vertebrates. A layer of smooth muscle cells is present with which the processes of the ganglion cells and the nerve fibres of the plexus are in connexion. Covering this layer of smooth muscle cells is a thin layer of connective tissue in which is found a more delicate nervous plexus, analogous to the plexus of Meissner, connected with the first plexus. The nature of the synaptic connexions of the dendrites of the ganglion cells with the nerve fibres of the plexus is discussed. The author is of opinion that there is a true syncytial synaptic connexion; he figures the synapses between dendrites of the ganglion cells and the nerve fibres, and states that there appears to be a real continuity of substance and especially of the neurofibrillar substance. He is totally against the presence at the synaptic junction of a dead intermediate substance of a sticky nature, as is maintained by some neuronists. The enteric plexus is connected by means of the visceral nerves and the dorsal roots with the central nervous system.

New Pinnotherid Crabs

NEW species of the genus *Pinnixa* are described by T. Sakai from Japan and by Steve A. Glassell from the Gulf of California (Science Reports, Tokyo Bunrika Daigaku, Section B, No. 29, Dec. 1934; and *Trans. San Diego Soc. Nat. Hist.*, 8, No. 5, March 1935). The genus consists of 34 species, three of which are fossil, and the species are mostly commensals of worm tubes and are found abundantly on the Atlantic and Pacific coasts of America. Only two have previously been reported from Japan, *P. tumida*, a commensal in the cloaca of *Caudina chilensis*, and *P. penultipedalis*. A third species formerly thought to be *P. occidentalis* is now found to be new, and the author proposes for it the name *P. rathbuni*. He now adds two new species, *P. balanoglossana*, living as a commensal in *Balanoglossus misakiensis*, and *P. haematosticta*, which was collected among dead shells. A key to all these species is given and a description of the new forms. The preliminary descriptions of *P. abboti*, *P. fusca* and *P. felipensis* by Mr. Glassell do not mention any hosts. Fuller descriptions and figures will be published in his forthcoming partial revision of the genus.

Propagation of the Hyacinth

THE *Gardeners' Chronicle* of August 3 contains an interesting article on "British-Grown Hyacinths" by Mr. D. E. Horton. Various aspects of the British trade in bulbs are reviewed briefly, but a large part of the paper is devoted to a description of methods of propagation of the hyacinth. The older method was to make three V-shaped cuts across the root-plate of the bulb, then place it in sand to callus, store it at a warm temperature with suitable humidity, when bulbils would appear at the bases of the scales. A newer method is to scoop out the root-plate with a special knife, and to follow with similar storage conditions. Scooping gives an average of 60–80 bulbils per plant, whilst cross-cutting usually yields only about 20. Moreover, the scoop-formed bulbils make their own roots, whilst cross-cutting produces roots from the mother bulb. Commercial practice suggests, however, that it is best to scoop strong varieties and to cross-cut slower propagators.

Longevity of Fungi

AN interesting paper by Ö. Winge and Aase Hjort, describing experiments on some ancient cultures of fungi, has recently appeared (*C. R. Trav. Lab. Carlsberg, Série Physiologique*, 21, No. 2, pp. 51-58, 1935, "On some Saccharomycetes and other Fungi still alive in the Pure Cultures of Emil Chr. Hansen and Alb. Klöcker"). Winge used cultures 16–17 years old, whilst Hjort, continuing the same investigation, had cultures 31 years old. The Carlsberg Laboratory possessed the original pure cultures, and these have now been tested for vitality by the authors of the paper under review. The oldest living cultures, of a species of *Zygosaccharomyces*, date from 1886—a span of forty-seven years, whilst *Saccharomyces Pastorianus* and *S. validus* had retained vitality for forty-five years in 1934. Solutions of 10 per cent saccharose or beer wort were the culture media employed, whilst Pasteur flasks reduced evaporation to a minimum.

Sediments in the Atlantic Ocean

IN the first part of "Die Sedimente des Äquatorialen Atlantischen Ozeans" (Wiss. Ergebn. d. Deutschen Atlantischen Exped. auf dem Forschungs- und Vermessungsschiff *Meteor*, 1925–1927, 3, No. 3, Lief. 1. Berlin and Leipzig: Walter de Gruyter and Co.) an account is given by Dr. C. W. Correns of the methods of collecting the bottom samples, which were taken on a series of traverses between 10° S. and 20° N., and of their examination both on board ship and afterwards. Estimates were made of the hydrogen ion concentration, carbonate, organic matter, manganese, titanium, iron and phosphorus, etc., as well as of particle size, and the comparison of the latter in fresh and preserved samples is particularly useful. An account is also given of the use of X-ray analysis for the detection of the mineral constituents. The second part, by Dr. W. Schott, describes the distribution of the pelagic foraminifera in the surface waters and in the bottom samples. In the former, their distribution seems to be conditioned by the temperature and phosphate content. Stratigraphically the cores show three layers,

distinguished by their *Globorotalia menardii* content, and probably deposited respectively before, during and since the last ice-age.

Water Exchange through the Straits of Dover

VARIATIONS in the exchange of water between the English Channel and the North Sea have a profound effect on the development there of young fish and of the planktonic animals on which fish feed. Dr. J. N. Carruthers has now published his second report on "The Flow of Water through the Straits of Dover as gauged by Continuous Current-meter Observations at the Varne Light-Vessel" (Min. of Agric. and Fish., Fish. Invest., Series II, 14, No. 4; 1935), which contains data for 1928–35. Considerable variations have been found in the average set of the current in different years and at different seasons. A marked loss of easting in the current distinguishes the last four from the first four years of the observations, and this fits well with other records of a change in the nature of the waters bathing the south and east coasts of Great Britain. Interesting relations have emerged between the Dover Straits current on one hand and the current round the north of Scotland and the success or failure of herring, plaice, cod and haddock year classes on the other.

Ray Tracks in Photographic Emulsions

H. J. TAYLOR (*Proc. Roy. Soc.*, June 1) has investigated the tracks of α-particles and protons in photographic emulsions, and A. Jdanoff (*J. Phys.*, June) has also worked on this problem. The tracks consist of developable grains, spaced a few microns apart, and are of length corresponding to the range of the particles in the emulsion. Taylor was able to obtain a special emulsion from Messrs. Ilford which was remarkably free from any background of spurious grains. With these plates, all the grains struck by an α-particle became developable, but only a proportion of those struck by a proton. The density of the grains along the track may be used to distinguish between proton and α-tracks. The plates were used to detect the H-particles knocked forward in neutron-hydrogen collisions, but Mr. Taylor thinks the uncertainties of the method do not allow it to be used for the determination of the distribution in detail of neutron energies. Jdanoff uses emulsions specially made to register H-particles and examines the tracks by a stereoscopic microscope method, which helps him to distinguish tracks from chance agglomerations of particles. He claims to be able to detect collisions and disintegrations, just as in the Wilson chamber.

The Oxide-Coated Cathode

M. BENJAMIN, working in the G.E.C. Research Laboratories, Wembley, has investigated the effect of additions to the nickel cores on the thermionic emission from oxide-coated cathodes (*Phil. Mag.*, July), and has found that some metallic additions can profoundly affect the emission. The proportion of added metal was of the order 0·5 per cent. Titanium was found to increase the emission, manganese and iron reduce it, while magnesium produces a temporary increase. It is suggested that the increase is brought about by the reduction of the barium oxide coating by the metal of the core, giving an increased concentration of active barium metal in the coating. This view is supported by the high emission obtained from a filament coated on a case containing the very potent reducer aluminium. During the course of the measurements, it was also found that the oxide-coated filaments fail to show saturation emission at very low temperatures, and this phenomenon is correlated with the change from electronic to electrolytic conduction through the coating as the temperature is lowered. In filaments containing aluminium or titanium, the higher barium concentration results in the electronic conductivity persisting to lower temperatures, and these filaments show saturation at lower temperatures than a pure nickel filament.

β-Glucosidase of Sorghum

ALTHOUGH Emil Fischer regarded α- and β-glucosidases as two distinct enzymes, and this view is supported by a number of recent observations, evidence may be found in the literature which suggests the possible identity of the two enzymes. Of interest in this connexion are the results of experiments on the β-glucosidase of *Sorghum saccharatum*, carried out by C. Antoniani (*Rend. R. Ist. Lombardo Sci. e Lett.*, 68, parts 6–9). The β-glucosidase examined was obtained either by macerating the ground, germinated sorghum seeds with water in presence of toluene, or by extraction with ammonia solution, followed by purification with acetic acid and alcohol. The velocity of hydrolysis of cellobiose by the enzyme is at first greater than that of salicin, but after 15 per cent of the substrate has been hydrolysed, the position is reversed. The action on salicin is somewhat retarded when glucose, but not when galactose, is added. It appears, from the results obtained, that the sorghum seeds contain an emulsin devoid of β-galactosidase.

Greenwich Catalogue of Stars

THE "Second Greenwich Catalogue of Stars for 1925.0" has been published by H.M. Stationery Office. Part I contains the Right Ascensions and Declinations of 2,111 fundamental stars, observed during the years 1922 to 1930, reduced to the equinox of 1925.0, and Part II contains similar data for 10,584 stars in the zone + 32° to + 64° observed in the same interval. In both cases, Newcomb's precession and Boss's proper motions have been used in effecting the reduction to the adopted equinox (that of 1925.0). The Right Ascensions adopted for the clock stars are those of the Greenwich observations of 1915–1921. A correction to Newcomb's equinox, namely, − 0·050^s, has been adopted in forming the catalogue. Every catalogue star has been observed at least five times in the period 1922–1930. The observations have been made with Airy's transit circle, which itself dates from 1850, and is responsible for the earlier Greenwich catalogues which have been incorporated in the data for proper motion. Although the telescope is the same, the modern observations are much more accurate on account of the application of the impersonal micrometer. In computing the proper motions, a modern place has been found for each star by combining the two most recent catalogues of Greenwich (including the present volume), the Cape, and Pulkova. The star's position for 1875.0 is worked out from the information available in eighteen catalogues, including earlier Greenwich catalogues, made about that time. The probable error of a proper motion varies from 0·001″ to 0·010″ according to the number of observations that have been made at one observatory or another.

Chemical Industry in the United States

PERHAPS the most remarkable thing about the meeting of the American Chemical Society held in April last in New York, and widely heralded as the "Official Tercentenary" of American chemical industry, was the presence of more than 25 per cent of the very large membership, some 17,000, of that Society. No body in Great Britain can count on such loyal support, and it affords a fine illustration of that 'working together' spirit which is carrying the chemical industry forward, so far and so fast, in the United States. Naturally the fare provided was very varied, though by collecting the papers into appropriate groups, it was possible for those with similar interests to forgather.

The social side was well to the fore, a feature being the replacement of elaborate and costly functions by a series of breakfasts, luncheons and dinners, arranged for the alumni of the numerous universities.

The opportunity for propaganda was not missed, including on one hand addresses of a general or topical character delivered by the leaders of the industry, whilst the Press was supplied with a large amount of suitable copy portraying the popular aspect and utility of the work of the chemist. They do these things well in New York under the guidance of the veteran secretary, Mr. Charles L. Parsons, and it is probable that nothing was left undone to make the meeting a gigantic success. It is worthy of comment that all the meetings could be held in the Hotel Pennsylvania, whilst the many delegates could be housed there and in three neighbouring hotels, all connected by underground passages.

Apparently the American chemical leaders are not afraid to criticise the administration. Mr. William B. Bell, president of the American Cyanamide Company, whose theme was "Recovery—by Alchemy or Chemistry", claimed that there is too much Government planning and too much Government waste; the one sound basis of industrial planning being that of purchase and sale, or profit and loss with no political interference or domination. A director of the Du Pont Company claimed that they are on the way to establish an American synthetic rubber industry, and that this has been made possible by the experience gained in the dye industry, which in particular must be in a position to expand quickly in a national emergency to make a variety of essential organic substances.

Emphasis was also laid on the popular use and significance of vitamins, preparations containing such now having the third largest sale in the drug stores.

As a novelty, it was proclaimed that young cereal grasses cut just prior to jointing have, when dry, a biological value many times that of the common vegetables and that men and women will be eating grass in the near future.

Altogether as wide a range of subjects were discussed as must have been dealt with in that famous conversation between the Walrus and the Carpenter —"and why the sea is boiling hot and whether pigs have wings".

Third International Congress of Soil Science

FIFTY countries were represented among the four hundred delegates who attended the Third International Congress of Soil Science held in Oxford on July 30–August 7. The occasion afforded an unrivalled opportunity for discussing the many aspects presented by every problem in soil science, but differing widely according to the geographical region in which the problem is studied. One of the most urgent needs of the science is to break down the parochial barriers which necessarily limit the views of workers confined to one climatic or physiographic region, and faced with the whole-time task of economically justifying their existence. That parochialism exists was amply evident at the Congress, as also were the difficulties of overcoming it; but it was equally evident that the holding of an international congress is a practicable means of producing some kind of order among the conflicting theories held by the world's most eminent pedologists.

The discussions brought into prominence several new directions in which this young science is developing. In the Soil Physics Section, the main interest centred round problems of soil moisture, and Dr. R. K. Schofield introduced a '*p*F' scale which precisely specifies the degree of wetness or dryness of a soil in much the same way that Sørensen's *p*H scale specifies the degree of acidity or alkalinity. The *p*F is the (positive) logarithm of the amount by which the free energy of the water in the soil is less than that of water in bulk at the same temperature and external pressure expressed as the height in centimetres of a water column. 1 cm. above a free water table is, therefore, *p*F0 while the 'oven dry' state is approximately *p*F7. The use of this scale enables a great mass of hitherto unrelated data to be welded together to make an orderly picture of aspects of soil moisture behaviour which are of special importance in irrigation. Dr. Schofield stressed the necessity of recognising hysteresis in the relationship of *p*F to moisture content, which he regards as due mainly to microplastic resistance to swelling and shrinking.

In the Chemistry Section much attention was directed, as usual, towards the base-exchange properties of soil colloids, particularly from the mineralogical point of view. The structure of montmorillonite and beidellite, as proposed by Hofman, Endell and Milne, was discussed, and Dr. C. E. Marshall showed that the apparent contradictions between their structure and the chemical formulæ can easily be removed by considering the operation

of certain replacements, aluminium for silicon in beidellites, and magnesium for aluminium in montmorillonites. Prof. C. H. Edelman proposed an alternative explanation for the base-exchange properties of the clays, having special reference to halloysite, which he regards as having marked exchange properties.

The Soil Fertility Section held a noteworthy discussion on the methods of estimating the manurial requirements of soils. Prof. E. A. Mitscherlich presented the first results of a great co-operative investigation, in which already 120 soils from different parts of the world have been studied, using more than thirty different methods. This investigation is a model of what can be attempted by international co-operation. Prof. O. de Vries surprised his hearers with an account of the number, running into tens of thousands, and the scope of the field experiments which have been made in the Dutch East Indies. Prof. R. A. Fisher followed this practical account by demonstrating the principles upon which the design of field experiments must be based if their results are to be of any real value. He made clear what is often overlooked, that accuracy alone is not enough, unless the *degree* of accuracy is also known. The very large number of papers dealing with the practical side of soil science which were presented to the Soil Fertility Section emphasised the dominating influence exerted on the development of soil science by modern economic conditions.

This was also apparent in the Soil Classification and Genesis Section. Hitherto the chief object of this section has been to establish an objective basis for soil taxonomy, but the principal matter discussed at Oxford was land rather than soil classification. An excellent series of papers described the methods adopted, with special reference to land settlement plans, in the United States, Canada, Germany and Hungary. Aims and methods differ widely in different countries, and are influenced by modern political trends towards national agricultural planning. The results can scarcely be regarded as objective, but they afford an illustration of the way in which an adolescent science may become involved with a transient political economy. That soil science has become a junior and sometimes fortunately forgotten servant of politics is recognised by research workers striving in many countries to make bricks without straw—to produce the practical results demanded of them with insufficient knowledge of the fundamental nature of the soil. Spectacular successes are still occasionally obtained (though none was described at the Congress) by applying the principles of pure chemistry, physics and biology to soil problems, but the field for such successes is narrowing rapidly, and it seems as if the next real step forward in either pure or applied soil science must be awaited until conditions allow research workers to reason out their problems from the beginning instead of from the end. The general impression left by the Congress was that practice has outstepped theory, and that there is little immediate likelihood that the discrepancy between them will be reduced.

The Radio Exhibition at Olympia

A VISIT to this year's Radio Exhibition at Olympia, organised by the Radio Manufacturers' Association, gave the impression that the broadcast receiver industry is at last beginning to outgrow its somewhat hectic childhood days, and is settling down to a policy of steady progress and development. On this occasion, the show was conspicuous by the almost complete absence of those 'epoch-making inventions', which in the past have involved the coining of new and wonderful names and the development of complicated valves, in an attempt to improve what has so often been termed 'perfect' reception.

The receivers exhibited fall approximately into three fairly distinct classes. The first involves the modest set of three or four stages with straight amplification at radio frequencies, at a price ranging from about five guineas. The second class includes the more elaborate supersonic heterodyne receiver, which combines the advantages of greater sensitivity and selectivity, and which in table and console models can be obtained at prices from ten or eleven guineas upwards. The third involves the incorporation of this receiver into the modern radio-gramophone which, in its more ambitious examples, commands a price ranging from twenty-five to well over a hundred guineas. While all these types of receiver have been available in previous years, the present display showed that the designers and manufacturers are overcoming the difficulties, technical and otherwise, which they have hitherto experienced in the mass-production of a rather complicated piece of radio apparatus. All but the simplest sets now incorporate such features as second-channel suppression, automatic volume control and some device to simplify tuning; while, from the musical listener's point of view, a welcome advance is the incorporation of variable selectivity in the better-class receivers. The general listener is not seriously interested in wavelengths, and to meet this point, it was noticed that there is an increasing tendency on the part of manufacturers to engrave tuning dials with the names of broadcasting stations. While also some firms have made a commendable effort to provide enlarged and improved scales, the indications of which can be read at a glance, in some cases a reminder would appear to be justified to the effect that the ordinary listener is not usually equipped with a pocket magnifying glass. Such a reminder is becoming increasingly necessary now that several receivers are provided with one or two short-wave ranges, in addition to the medium and long-wave ranges. This provision is a welcome addition to this year's sets, and indicates an increased tendency to listen to programmes emanating from stations outside the continent of Europe.

A feature of the exhibition, which is perhaps somewhat significant, was the almost entire absence of any reference to television. One or two firms showed components specially designed for use on ultra-short waves in anticipation of experimenters' requirements, especially when a television service is commenced on

wave-lengths less than ten metres. On the whole, however, it was evident that the industry desires to remove from the minds of the public any tendency to delay the purchase of a new receiver on account of the inauguration of a television service in the future. It is unlikely, of course, that this service will in any way affect the use made of the ordinary set for the reception of sound programmes.

Another noteworthy and very recent development, shown for the first time at a radio exhibition, was a series of midget valves, about two inches or less in length and half-an-inch in diameter. These valves have now been placed on the market and are supplied in patterns of the triode, screen-grid and pentode types, with characteristics comparable with those of ordinary commercial valves. They are of very robust construction and are supplied with neat bases of either bakelite or steatite, the latter being specially suitable for the application of the valves to ultra-short wave working. Valve-holders are also available in either material. The production of these valves has given an impetus to the development of midget receivers, several types of which were displayed at the exhibition. One case is literally a pocket receiver, its dimensions being 6 in. × 4½ in. × 1⅛ in., and its weight 2 lb., complete with all batteries and frame aerial. This set is used with a single telephone receiver and is claimed to have a normal receiving range of 50–100 miles on the medium wave broadcasting band. It is known that such receivers have been in use by police forces for some time; but they have not hitherto been generally available to the public. Another receiver, employing four midget valves, weighs 9 lb., and its dimensions are about 9 in. square by 5 in. deep. This contains its own frame aerial, batteries and loud speaker, and since in size and appearance it is much like a box camera, it offers a new conception of the term 'portable wireless set'.

Readers of NATURE who are interested in obtaining further information on any items mentioned above or other matters covered by the Radio Exhibition will be assisted by reference to the Exhibition numbers of the *Wireless World* or *World Radio* (issues dated August 16 and 23 in each case).

The State of Flowering known as Angiospermy

UNDER this title, Prof. J. McLean Thompson makes a very interesting contribution to current speculations as to the nature of the carpel (Publ. Hartley Bot. Laboratories, No. 12, University Press of Liverpool, 1934). His views are based mainly upon developmental studies and close comparative studies of types within a limited range of affinity. These are sound grounds upon which to base morphological conceptions, and they require careful consideration, even if at first view they run directly counter to many popular conceptions.

The flower is regarded essentially as an axis of limited growth with a potentiality to produce sporogenous tissue. This growth centre earlier was vegetative, and the transition to sporogenous growth activity is indicated by the transitional region of bracteoles, sepals, etc.; similarly, the zone between two types of heterosporous tissue may be marked by carpellary structures bearing anthers; the essential fact is the tendency to bear sporogenous tissue upon an axial emergence which may take various forms.

A series of monocotyledonous forms with inferior ovaries is studied, with the result that no ground is found in their development for the view that the placentæ should be regarded as the ingrowths of the walls of sunken carpels. Rather there is extensive toral growth that gives an ovary wall; on the inner rim of this are outgrowths, of which nutrition is often defective and which may be interchangeably style or staminode.

In the same way, a study of the superior apocarpous gynæcium in the Ranunculaceæ suggests that the follicle is to be regarded as a toral upgrowth, after apical growth of the axis has ceased, which links together several associated primordia of a complex spiral phyllotaxis, primordia which lower on the axis would bear anthers and now are associated in the production of ovules. Similarly, the carpels of the *Ranunculus* flowers are the upper members of orthostichies which lower on the axis are represented by stamens; these upper members are essentially sporogenous, and in their central position bear ovules.

Educational Topics and Events

DR. NICHOLAS MURRAY BUTLER'S report for 1934 on the Carnegie Endowment for International Peace, Division of Intercourse and Education, is a very interesting record of extensive and carefully organised propaganda in the United States of America, in Europe, in Latin America and in the Orient. In the United States, the Endowment's doctrine of international co-operation as the normal method of conducting world affairs in lieu of the rule of force finds ready acceptance in universities and in educational circles generally: the difficulty is how to reach the people whose opinions have decisive weight when it comes to divisions in Congress and Senate. The 36 Senators who on January 29, 1935, voted against the ratification of the World Court Protocol, so that the affirmative majority fell short of the requisite two-thirds, prevented their Government, the report points out, from co-operating effectively in an important application of this doctrine—a heavy responsibility. International relations clubs, which are groups of students meeting regularly with a faculty adviser, increased during the year in universities and colleges on the United States by 53, making a total of 523. In addition, the movement extended to high schools, in which more than a hundred clubs have been established. The Endowment co-operates by presenting books and other material with the object of giving that background of facts which will enable students to read more understandingly the international news and exert a wider influence after leaving school and college. Outside the United States, 130 such clubs have been formed during the past four years in 29 countries, among which the only European countries are Bulgaria, Great Britain and Greece. Among publications for which the Endowment is responsible are "International Conciliation" and "L'esprit international". The work of the Division in Europe is conducted from Paris (173 Boulevard St. Germain) by a Directeur-Adjoint with the help of a committee representing Austria, Belgium, France (3), Germany (2), Great Britain (2), Greece, Hungary, Italy (2), Spain and Switzerland.

SCIENCE versus superstition in China has not the news-value of the wars of the war-lords, but it is a conflict of which the issues are probably of far greater moment. A letter from Peiping Union Medical College published in *School and Society* of March 30 gives some idea of the strength of the defensive positions which bar the progress of Western science in that country. Every year a considerable number of natives of China graduate at universities in Europe and America and return to their native land with the object of entering upon the practice of medicine or engineering or whatever other profession they have been qualifying themselves for. Provided they are content to settle in one of the coastal cities, they have every prospect of establishing themselves in lucrative and honourable positions, in which they will have ample scope for demonstrating the value to the community of their newly acquired Western knowledge and training. But once they venture into the interior of China, they find themselves up against the most baffling obstacles. Their attempts to apply scientific methods are met with distrust, contempt and ridicule; a mass of deeply entrenched vested interests is stirred into activity; they find their plans thwarted by intrigues and their young enthusiasm speedily evaporates. For in the majority of cases, such students get their first effective contact with Western ideology when they are already about sixteen years of age and consequently they suffer, on repatriation, from "a basic lack of confidence in the fundamental truth of that which they have learned abroad". There has been little or no common ground between the culture absorbed in childhood and the new culture, with its radically different modes of expression, picked up in the West. For the moment, the situation is not encouraging for those who have striven to provide a nucleus of foreign-trained Chinese with whose help China could learn to help herself.

Science News a Century Ago

Memorial to Watt at Greenock

THE issue of *The Times* of August 24, 1835, reported: "The Committee appointed to conduct the erection of the Watt monument and public library at Greenock have with the approbation of the Provost and magistrates of Greenock, and the most worshipful the Provincial Grand Master for Renfrewshire resolved that the foundation stone of the monument be laid with masonic honours on Tuesday, 25th inst. The mason lodges, corporate bodies and trades desirous of doing honour to the memory of Watt, in his native town, have determined on a public procession and the necessary arrangements are being made."

Fall of the Dent du Midi

ON August 26, 1835, "A considerable portion of the principal peak of the Dent du Midi, one of the great spurs of Mont Blanc, fell with a tremendous crash into a deep and narrow valley situate about a league to the eastward of St. Maurice, on the road to Martigny. An accident of a similar nature occurred in the year 1818 when no less than 400 houses were washed away. In this recent instance the peak in its fall carried with it a glacier, which, filling up the valley, dammed up the stream which ran through it, until it had acquired sufficient force to drive before it the whole mass of earth and rocks into the bed of the Rhone, the course of which became so completely barred as to dry up all below it, and convert the upper part of its rugged and rocky course into a sort of temporary lake. . . . It was not known that any lives had been lost, but the passage across the Alps by the great Simplon road was for a time cut off. An attempt was immediately begun to reopen the communication by a temporary road, which was to describe a considerable circuit." ("Annual Register".)

The Yaguarundi

"THIS beautiful species of *felina*, known only to naturalists by the description of it by Azara in his travels in South America," it is recorded in *The Times* of August 27, 1835, "has been brought for the first time to this country, and arrived last week in the Louisa Bailey from Guiana. It belonged to Mrs. Alboua, and has been presented by her to the Surrey Zoological Gardens. Its general form and character strongly resemble those of the puma, but having the limbs more slender in proportion to its size, the head more pointed, the strength of the jaws and teeth proportionately less, and the tail one-third of the animal's own length. . . . It is an inhabitant of the deep recesses of the forests of Paraguay and Guiana, climbing trees readily, and preying upon monkeys and small birds, but will boldly attack large quadrupeds. Its possession will form a valuable addition to our knowledge of the history of this genus of animal."

Halley's Comet seen in England

HALLEY'S COMET was first seen in England by Sir James South at Kensington, and then by the Rev. T. J. Hussey at Hayes Rectory. On August 31, 1835, *The Times* contained the following note: "Halley's Comet. Royal Observatory, Greenwich, Aug. 28. At 14 h. 7 m. 35.6 s. mean time, the right ascension of the comet was observed by the five feet equatorial to be 5 h. 47 m. 42.1 s. and declination 24 deg. 25 m. 33 s. north. It appeared very faint."

The Steamships of Great Britain

THE *Mechanics' Magazine* of August 29, 1835, gave some interesting particulars of the number and size of the steam vessels in Great Britain, and the ports to which they belonged. The figures had been taken from a return recently made to Parliament. The total number of steam vessels registered in Great Britain was 397 with a total tonnage of 36,849 tons. There were 84 steam vessels not registered, and 46 under construction. Of the ports, London was at the head of the list with 98 vessels of 11,785 tons and Glasgow second with 56 vessels of 5,298 tons.

The six largest vessels at the time were: *Monarch* of London, 587 tons; *City of Aberdeen*, 384 tons; *Dundee* of Dundee, 399 tons; *City of Hamburgh*, 380 tons; *Perth* of Dundee, 399 tons; *John Bull* of London, 398 tons. The registered tonnage, it was explained, was only about one third of the tonnage by admeasurement; and it was estimated that the aggregate tonnage of the steam vessels of Great Britain was about 100,000 tons. The sailing ship tonnage of Great Britain at this time was probably about 3,000,000 tons.

Societies and Academies

PARIS

Academy of Sciences, July 1 (*C.R.*, 201, 1–104). LOUIS BLARINGHEM: The duplication of the flowers of the wallflower (*Cheiranthus Cheiri*). JEAN REY: The energy yield of thermo-compressors. Definitions and values. The efficiency of a thermo-compressor can be defined in six ways, all rational. The values differ, and if the compressor is bought under guarantee, the exact definition of field must be specified. H. GRUYELLE and CHARLES POISSON: The magnetic anomalies of the crystalline massif of Madagascar. The magnetic survey by E. Colin between 1901 and 1906 gave magnetic charts of great complexity due to the presence of anomalies. These are now shown to be very local and are mainly due to the presence of magnetite in certain of the underlying rocks. ANDRÉ CARREL and CHARLES A. LINDBERG: The culture of entire thyroid glands. The thyroid gland, with its epithelial cells, its conjunctive tissue, arteries and veins, continues to live for at least 20–30 days under the conditions described in these experiments. Its structure, the structure and activity of its follicles vary rapidly with the chemical composition and the physical and physico-chemical conditions of the liquid circulating in the vessels. WALTER S. ADAMS was elected *Correspondant* for the Section of Astronomy in succession to the late F. Gonnessiat. PIERRE DAURE: Remarks on the validity of statistical conceptions applied to social phenomena. GARRETT BIRKHOFF: Discrete spaces. RAYMOND JACQUES: Certain systems of partial differential equations. ALFRED ROSENBLATT: The Green's function of a limited domain of Euclidian space of three dimensions. M. KREIN: 'Charged' integral equations. W. BŘEČKA: Multiply monotonic polynomials which deviate least from zero. FRÉDÉRIC ROGER: Some metric applications of the idea of the bilateral contingent. LARS AHLFORS: The type of a Riemann surface. ALBERT TOUSSAINT and MIROSLAV NÉNADOVITCH: Contribution to the study of certain rigid biplane cells of finite span. MAURICE DENIS: Contribution to the experimental study of sustaining wings at large incidences. E. M. ANTONIADI: Recent observations of the planet Mars with the 83 cm. telescope of Meudon observatory. The appearance of Mars shows no great difference from that shown in 1933. Details of the observations are given. FRÉDÉRIC MARGUET: The curve of equal azimuth and its use in navigation. GEORGES ALLARD: Statistical mechanics and the equilibrium of radiation and of matter. ANDRÉ LÉAUTÉ: The measurement of the surface tension of viscous substances such as tars and bitumens. Studies of the capillary tube method, paying special attention to the time necessary to attain equilibrium, one bitumen requiring 360 hours. Discussion of the causes of the large divergences between the results obtained by this and by other methods. CLAUDE CHARMETANT: The electrolysis of nickel and cobalt chlorides in solutions of mixtures of water and ethyl alcohol. HUBERT FORESTIER: Magnetisation at a high temperature of ferromagnetic powders. Powders (precipitated ferrites, oligist) heated to the temperature of the Curie point and cooled in a magnetic field showed residual magnetism. This is now shown to depend on three fundamental factors, strength of the field, fineness of the grains, and the crystalline structure. NICOLAS SZULC: Study of the structure of the electric arc. From the results of the experiments described it is concluded that the electric arc is divided into two parts: a conducting part where the electrical energy is partly used in producing dissociation of exothermic compounds and the formation of endothermic compounds, and a slightly conducting part where exothermic compounds are formed. HUA-CHIH CHENG and JEAN LECOMTE: The modes of vibration of the 1,2,dihalogen derivatives of ethane. The results tabulated are based on Raman spectra and maxima of infra-red absorption. MICHEL DUFFIEUX: The phosphorescence of nitrogen peroxide. The intensity of the bands of the second positive group of N_2. STÉPHAN PROCOPIU: The depolarisation of light by colloidal solutions, by crystalline precipitates and by solid deposits on glass. MAURICE LUCAS: The variation of the length of cement as a function of the hygrometric state of the air. The experimental results are given graphically in three curves, showing the change of length as a function of the weight of water absorbed, and as a function of the hygrometric state of the air, and the change of weight as a function of the hygrometric state of the air. JEAN MOLNAR: The physicochemical properties of picric acid in the *p*H scale. The experimental results can be explained on the hypothesis that picric acid passes through seven molecular forms with changing *p*H. PIERRE JOLIBOIS and FRANÇOIS OLMER: A new method of catalysis. Application to ammonia. ANDRÉ MICHEL and ANDRÉ GIRARD: Thermomagnetic analysis as a means of proving the existence of weak solid solutions of the oxides of iron. F. BOURION and E. ROUYER: The cryoscopic determination of the total hydration of the ions of magnesium chloride. JEAN BUREAU: The system calcium nitrite, water. MLLE. MARIE FALINSKI: The increase in the rotatory power of mannite by zirconium salts in aqueous solutions. MARCEL PATRY: The telluric acid group. Nomenclatures. T. KARANTASSIS and L. CAPATOS: The complex iodine compounds of divalent germanium. ORESTE MILLER and LÉON PIAUX: The Raman spectra of *meta*- and *para*-dimethylcyclohexane *cis* and *trans* isomers, and of 1,1,dimethylcyclohexane. CONSTANTIN GHEORGIU and MLLE. LUCIE MANOLESCU. Heteropolar combinations: complex salts of silver and mercury with 2,thio-4-hydroxy-1,2,3,4-tetrahydroquinazoline. CHARLES LAPP: The specific rotatory power of salts of quinine, quinidine, cinchonine and cinchonidine. PAUL BRENANS and PIERRE LARIVAILLE: Iodo-*m*-nitrophenols. EDMOND BOCQUIER: The existence of a group of large fossil cavities of the Monasterian epoch on the coast of Talmondais (Vendée). V. BABET and RAYMOND FURON: The continental post-Hercynian formations of the west of Africa (western Africa and equatorial Africa). MAURICE GENCE: The bases of the Klippes of Etienne-Encauron, to the north of Sainte-Baume. GEORGES DENIZOT: The successive tectonic phases in the neighbourhood of Marseilles. PIERRE URBAIN: The separation of the various constituents of marls. LOUIS DANGEARD: The black Eocene clays of the Londe forest (Lisieux geological sheet) containing algæ belonging to the genus *Botryococcus*. J. LEGENDRE: The maritime mosquito. BORIS EPHRUSSI and G. W. BEADLE: The transplantation of the imago discs in *Drosophila*. LOUIS COTONI and JACQUES POCHON: The application to antistreptococcic sera of a new method of titration by the neutralisation of the antibodies *in vitro*. RADU CODREANU: Malignant neoplasis in the hæmocœle of Ephemers under the action of *Symbiocladius rhithrogenae*, a Chironomid ectoparasite.

CAPE TOWN

Royal Society of South Africa, June 19. M. RINDL and M. L. SAPIRO: The alkaloids of *Strychnos Henningsii* (3). Isolation of a second crystalline alkaloid. On the basis of a large number of analyses of the crystalline alkaloid isolated both by the authors and by the firm of E. Merck, of Darmstadt, Germany, the formula $C_{22}H_{25}N_2O_4(OCH_3)$ is ascribed to this compound. This formula differs from the one previously suggested. The alkaloid is probably phenolic. The crude alkaloid is accompanied by very small quantities of a second alkaloid, which can be removed by continuous percolation with ether and purified by high vacuum sublimation. Analyses suggest a formula differing from that of the first crystalline alkaloid by an increment of CH_2. The likelihood is that the two alkaloids are the monomethoxy and dimethoxy derivatives of the same mother substance. There is also evidence of the presence of a third crystalline alkaloid. J. L. B. SMITH: The genus *Tripterodon*, Playfair. The fish *Triperodon*, the anatomy of which and taxonomic features have hitherto been inadequately studied, has been investigated. Morphologically it appears that it should be included in the family *Platacidae*. J. BURTT DAVY: *Taraxacum magellanicum*, Comm., in South Africa. S. BIESHEUVEL: The nature of temperament. The behaviour qualities grouped together under the heading of temperament have been reduced to three distinct units, for each of which a psychological explanation has been found. The relationship of these fundamental factors to environmental influences and organic processes has been tentatively determined. R. S. ADAMSON: Note on the stem structure of *Boscia rehmanniana*, Pest. The old stems have anomalous secondary thickening with successive extrafascicular cambia. These arise as separate portions and develop tissues both centrifugally and centripetally. The centrifugal growth is much greater than the centripetal.

GENEVA

Society of Physics and Natural History, June 20. M. GYSIN: The copper minerals of Kinsenda (Belgian Congo) (3). On the presence of a hypogene covelline and a supergene covelline. The author describes two varieties of covelline observed in the copper minerals of Kinsenda. The first variety forms lamellar inclusions in bornite, which start from the (100) cleavages to develop in the octohedral (111) directions; it is of hypogene origin. The second variety, of supergene origin, forms large tufts which spread over outside the grains of chalcopyrite and of white chalcosine, following generally the sphenoidal octohedral directions of the two minerals. TH. HILLER: (1) Contribution to the study of opaque minerals by the methods of impressions. Improvement in the technique of electrolytic attack. The author describes a technique for etching electrolytically and then taking a chemical print of the grains of isolated minerals in the gangue. This method allows opaque conducting minerals, completely refractory to ordinary chemical reagents, to be attacked, and shows their principal elements without destroying the specimens. (2) The determination of some linneites of Northern Rhodesia and Katanga by the method of imprints. The author describes the chemical reactions utilised for identifying cobalt and copper in some linneites with polished surface by the method of imprints. The simultaneous presence of these two elements is a character peculiar to linneite, and this permits its differentiation from a series of optically analogous minerals. P. WENGER, CH. CIMERMANN and MLLE. NYSZEWIANSKA: The micro-estimation of cadmium by means of oxyquinoline.

Forthcoming Events

Science and Leadership in Industry

THE industrial position of the north-east coast of England has been built up on the four basic industries of coal mining, iron and steel production, shipbuilding and ship-repairing, and marine and general engineering. These four industries are among those most severely hit by the post-War depression. The report on the industrial survey of the area conducted in 1931 for the Board of Trade by Armstrong College, Newcastle-upon-Tyne, stated that the problem facing these industries was one of the scaling-down to meet a diminished demand which is likely to be permanent, but suggested that with enterprise the north-east coast should retain its pre-War proportion of the total output of the whole country.

The report recognised, on the other hand, that there was little prospect of increasing that proportion, but pointed out that this depended on the amount of initiative shown by the industrial leaders in the area. This emphasis on leadership was repeated throughout the report. Development, it insisted, depended largely on the adaptation of existing works to new needs and new conditions; the industrial future of the area depended in the main on its own business leaders. Wherever possible they must call in science to their aid. In agriculture, as in industry, what was needed was the willingness and ability to appreciate new ideas, to adopt new methods and to try out new enterprises.

Memoranda contributed to the report cited examples of recent failures of industry in this area, particularly chemical industry, to meet these needs and to provide a broad and enlightened scientific leadership backed by adequate research. As example, reference was made to the failure of the Newcastle Chamber of Commerce to grasp the opportunities afforded by such developments as the manufacture of acetic acid and acetone, or the rayon industry, the synthesis of methyl alcohol and of liquid fuel from coal, all of which have since reached commercial production outside the area. The opinion was also given that the attitude of the shipbuilding industry towards research was not so favourable as it should be, and doubt was expressed as to whether without attention to research this industry would continue to lead the way. Prof. H. V. A. Briscoe insisted on the necessity for scientific invention and discovery to take the place that mechanical invention formerly held, and asserted that the chief hindrance to development lay in the fact that, in general, the directors and executive officials responsible for the policy and organisation of industry were unable to understand or appreciate scientific matters and methods, whether in technical manufacture or commercial operations. Because they did not really know or understand the basic scientific principles which underlie their operations, business men did not know enough either to seize the good or reject the bad when confronted with possible developments. He urged that business men should depute their task of consideration and decision in *technical* matters to scientific men who are also sound business men, though not necessarily having previous knowledge of the particular business.

The memorandum on science and industry which Prof. G. R. Clemo and Dr. J. T. Dunn have recently submitted to the District Commissioner for Depressed Areas at Newcastle-upon-Tyne, some points from which are described in an article on p. 323 of this issue of NATURE, indicates that unfortunately those warnings have as yet received little attention. The figures quoted in the memorandum relating to the employment of scientific

graduates in local industries indicate a most disappointing situation, even for a time of bad trade and general unemployment. Of 184 honours graduates in chemistry from Armstrong College, only a dozen secured industrial employment locally, although they were employed in large numbers elsewhere. In physics, only one out of thirty-nine honours graduates during the past five years obtained local employment in industry. Even in the applied sciences such as electrical engineering, only 20 per cent at most of the students are to be found holding local posts five years after graduating, in spite of the fact that about 85 per cent of them are attached to a works before entering college.

These figures in themselves are sufficient to suggest that neglect of scientific skill is one of the reasons for the industrial sickness on Tyneside, but other evidence also is quoted to show that the best possible scientific direction of industry is not exercised there to-day. Even if it be admitted that a committee of men of science may overestimate the importance of employing scientific workers, the instances cited of missed opportunities in regard to new developments in coal products as well as the continued absence of a definite centre for shipbuilding research and the neglect of valuable by-products of the fishing industry, show that lack of foresight and not the general absence of jobs is the real reason for the non-employment in the area of graduates in science.

The singularly slight use which Tyneside is making of its fine centre of scientific education in Armstrong College is not due to the recruitment of scientific staff from other universities, for no case of any such appointment was discovered in the inquiry. Moreover, there is evidence of a similar neglect of technical education, and the absence in the district of any chair founded or laboratory built and endowed by industrialists, as are to be found at Manchester or Liverpool, for example, is further significant confirmation of the inadequate recognition of the importance of industrial development.

In contrast with the present position, it must be remembered that the alkali industry of the north-east coast of England was founded and carried on by men who made the best use of the science of their time ; for long it was a source of prosperity to the district. The Newcastle Chemical Society was founded in 1868 and was a highly flourishing society when its membership in 1883 became the nucleus of the Newcastle Section of the present Society of Chemical Industry. Moreover, the whole area, with its natural advantages in the situation of coalfields and ironworks, enjoyed its full share of prosperity during the first part of the industrial revolution.

The indictment brought forward in Prof. Clemo and Dr. Dunn's memorandum is thus supported by far too convincing evidence to be lightly dismissed. While no one reason will account for the decline of the area, a great factor has been a narrow outlook which failed to recognise that industry is based on science, and that a policy which drains the profits and leaves insufficient resource for research and development is doomed ultimately to failure. The ease with which success has been gained in the past has induced the leaders of industry on Tyneside to rest too readily upon their laurels.

Lack of foresight as an outcome of prosperity experienced a generation or two ago is not confined to Tyneside. Similar charges have been brought against the textile industry in Lancashire, particularly of the neglect of technical training and the use made of juvenile labour. In his jubilee lecture to the Society of Chemical Industry this year, Mr. C. J. T. Cronshaw showed how the decline of the early dyestuffs industry in Great Britain could be traced to an exactly similar lack of foresight on the part of its leaders, and under modern conditions industry more and more demands this quality of foresight. As successive reports of the Department of Scientific and Industrial Research have emphasised, industry in Great Britain can only meet the fierce competition to which it is now exposed by a determined and persistent effort to apply the results of research and scientific discovery both to the cheapening and improvement of existing products and the development of new ones, as well as to the exploration of the natural resources of the country, combined with close attention to the question of technical training, efficient organisation and management. The nation cannot, in fact, afford to allow industry to be retarded by leaders who have lost the capacity of foresight and leadership, and whether in the depressed areas or elsewhere means must be found of rectifying the position.

So far as defective industrial leadership has contributed to the present position on Tyneside, it is probably not too late for a number of remedial measures to be applied. The various memoranda presented to the District Commissioner indicate several directions in which investigations could profitably be initiated, and the District Commissioner

is unlikely to be without either the power or inclination to effect some of the obvious reforms. The great enterprise of Imperial Chemical Industries, Ltd., at Billingham, which has been carefully exempted from the Committee's argument, provides a stimulating example of what is possible when foresight and vigorous leadership are forthcoming.

On the general body of scientific and technical opinion in the area, however, as well as in the rest of the country, a special responsibility rests. Whatever reforms may be imposed by the District Commissioner from above, it is only as scientific workers complete the task of education initiated by this joint committee representing the local sections of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, that we can expect to see the fullest and most scientific use made of the resources of the area either in materials or in man-power. From their ranks inevitably must be drawn many of the future leaders. For many years they may be called upon to exercise those advisory functions suggested by Prof. Briscoe, and it is only as they insistently support the arguments advanced by Prof. Clemo and Dr. Dunn that we can hope to see the habits and prejudices of years broken down and replaced by more enlightened ones.

The action taken by this Joint Committee provides an example of the ways in which scientific workers can serve the needs not merely of the special areas but also of the whole country, an example fully as inspiring as that already provided in the industrial surveys carried out for the Board of Trade. Through this work their special knowledge no less than their civic zeal should find ample employment. In thus emphasising the practical directions in which developments are possible and the part which science has to play in industrial leadership and development, they will go far towards meeting the first need of these special areas in bringing them hope and creating work.

The Basis of Modern Mathematical Analysis

Inequalities

By G. H. Hardy, J. E. Littlewood and G. Pólya. Pp. xii+314. (Cambridge: At the University Press, 1934.) 16*s*. net.

INEQUALITIES, as opposed to equalities, may be said to form the basis of modern mathematical analysis. The arithmetical definition of a limit is itself based upon the idea of inequality, and in the hands of the school founded by Weierstrass and his successors has removed from analysis the vagueness and mystery which were due to appeal to an indefinitely qualitative idea of continuity. A book on inequalities by three leading mathematical analysts is therefore an event in the realm of mathematical literature, the more so since no book on this subject has been published before.

The book was originally planned to form one of the Cambridge Tracts; but the authors soon found that a larger work would be necessary to fulfil the ideals which they had in view. These ideals demand a complete discussion of the important elementary inequalities by the most elementary methods appropriate to the case and an exhaustive enumeration of the cases where inequality degenerates into equality. Thus Cauchy's inequality

$$(\Sigma ab)^2 < \Sigma a^2 \Sigma b^2,$$

unless (a) and (b) are proportional, is a proposition of finite algebra (in the case of finite sums) and the proof should involve only the methods of that theory. Cauchy's inequality is itself a particular case of Hölder's inequality

$$\Sigma ab < (\Sigma a^k)^{1/k} (\Sigma b^{k'})^{1/k'},$$

where $k > 1$, $k' = k/(k-1)$, unless (a^k), $(b^{k'})$ are proportional. An inequality equivalent to Hölder's is

$$\Sigma a^\alpha b^\beta < (\Sigma a)^\alpha (\Sigma b)^\beta,$$

unless (a) and (b) are proportional, where α, β are positive and $\alpha + \beta = 1$. When α is rational this is also a theorem of finite algebra. When α is irrational a^α is not an algebraic function and a step outside algebra must be taken. If we define a^α as $\exp(\alpha \log a)$ the proof must necessarily involve the theory of the exponential and log arithmetic functions and this should be the only step outside algebra which is taken in the proof. On the other hand, if we define a^α by

$$a^\alpha = \lim a^{\alpha_n},$$

where (α_n) is a set of rational numbers whose limit is α, then the proof should involve an appeal to this limiting property alone. Here, however, another difficulty arises. Assuming the inequality to have been proved for rational α, in the passage

to the limit the sign $<$ becomes $\leqslant$, whereas the sign should still be $<$, so that the proof is incomplete. The difficulty can be turned by putting $\alpha = \gamma + \lambda$, $\beta = \delta + \mu$ where γ and δ are rational. Then, if $\gamma + \delta = \varepsilon$, $\lambda + \mu = \nu$,

$$\Sigma a^{\alpha} b^{\beta} = \Sigma (a^{\gamma/\varepsilon} b^{\delta/\varepsilon})^{\varepsilon} (a^{\lambda/\nu} b^{\mu/\nu})^{\nu}$$
$$\leqslant (\Sigma a^{\gamma/\varepsilon} b^{\delta/\varepsilon})^{\varepsilon} (\Sigma a^{\lambda/\nu} b^{\mu/\nu})^{\nu}$$

But $\Sigma a^{\gamma/\varepsilon} b^{\delta/\varepsilon} < (\Sigma a)^{\gamma/\varepsilon} (\Sigma b)^{\delta/\varepsilon}$, and a similar inequality with $\leqslant$ for the other sum. The theorem then follows by combination of these results. The same difficulty arises in the passage from a finite inequality to one involving infinite series or integrals. It is therefore important to frame proofs in such a manner as to avoid a passage to the limit whenever possible.

The first part of the book, Chapters ii–vi, aims at a systematic treatment of inequalities centred round the three fundamental inequalities: (1) The theorem of the arithmetic and geometric means; (2) Hölder's inequality; (3) Minkowski's inequality, namely,

$$\mathfrak{M}_n (a) + \mathfrak{M}_n (b) > \mathfrak{M}_n (a + b), \; n > 1,$$

where the symbols refer to the weighted mean

$$\mathfrak{M}_n (a) = \left(\frac{\Sigma p a^n}{\Sigma p} \right)^{\frac{1}{n}}$$

The apparently exceptional position of the geometric mean is elucidated by theorem 3, where the geometric mean is shown to be

$$\lim_{n \to 0} \mathfrak{M}_n (a).$$

In Chapter iii the idea of means formed with an arbitrary function $\varphi(x)$ is introduced by the definition:

$$\mathfrak{M}_{\varphi} (a) = \varphi^{-1} \left(\Sigma q \varphi (a) \right), \; \Sigma q = 1,$$

the arithmetic and geometric means corresponding respectively to the functions x^n, $\log x$. The question of the comparability of two means formed with functions $\varphi(x)$, $\psi(x)$ leads to a discussion of the properties of convex functions and to generalisations of Hölder's and Minkowski's inequalities.

In Chapter v, theorems relating to finite sums are extended to infinite sums, the general conclusion being that such extensions are valid in so far as they retain significance. The corresponding extensions for integrals are carried out in Chapter vi. A simple example of the avoidance of a passage to the limit is furnished by the proof of Schwarz's inequality

$$\left(\int f g dx \right)^2 < \int f^2 dx \int g^2 dx,$$

which follows from the statement that the quadratic form

$$\int (\lambda f + \mu g)^2 dx = \lambda^2 \int f^2 dx + 2\lambda\mu \int f g dx + \mu^2 \int g^2 dx$$

is positive and therefore has a negative discriminant. Equality can only arise when constants λ, μ, not both zero, exist such that $\lambda f + \mu g = 0$. When the integrals are Lebesgue integrals, this means that $\lambda f + \mu g = 0$ almost everywhere. By adopting Lebesgue-Stieltjes integrals (which include sums) the statement of dual theorems for sums and integrals can be avoided, and the theorems stated for integrals only.

The remaining four chapters constitute a series of essays on subjects suggested by the first six, and are intended as an introduction to certain fields of modern research. These chapters are full of interest and make accessible a large number of results scattered in mathematical periodicals.

Chapter viii deals with some properties of multilinear and bilinear forms, with interesting particular theorems on forms in [2, 2] Hilbert space. Incidentally, the y_j at the top of page 213 should be x_j.

Chapter ix contains a valuable discussion of Hilbert's inequality with its analogues and extensions. Hilbert's inequality is

$$\Sigma\Sigma \frac{a_m b_n}{m + n} < \frac{\pi}{\sin (\pi/p)} (\Sigma a_m^p)^{1/p} (\Sigma b_n^{p'})^{1/p'}$$

where $p > 1$ and $p' = p/(p - 1)$. Much work had to be done before this final form was attained. The theorem is made to depend upon a more general result, due to the three authors, of which an elegant proof is given. The constant π cosec (π/p) is the best possible, that is to say, it cannot be replaced by a smaller number.

Chapter x deals with rearrangements. The simplest problem of this kind is to find the arrangement of the sets (a), (b) which makes Σab greatest. The answer is, of course, when the two sets are monotonic in the same sense. The corresponding extensions to three or more sets, and the idea of rearrangements of functions of a continuous variable lead to extremely subtle and entertaining arguments.

The authors are to be congratulated on a masterly presentation of a subject which is as fascinating as it is useful to the mathematician. The applied mathematician will be interested to see theorems 216, 217, 218.

The printing is excellent, but it is a pity that bolder type was not used to distinguish the numbers of the theorems, which are in the same type as the paragraph numeration and exasperatingly difficult to find.

The book will form an indispensable addition to every mathematician's library.

L. M. M-T.

Grasses

The Gramineae: a Study of Cereal, Bamboo and Grass

By Dr. Agnes Arber. Pp. xvii+480. (Cambridge: At the University Press, 1934.) 30*s*. net.

GRASSES probably now constitute quite as large a family as the orchids, and no group of flowering plants includes so great a number of individuals as the Gramineæ. They are by far the most important from an economic point of view, whilst many botanists regard them as representing the peak of evolution among flowering plants. For grasses are found almost everywhere, occurring in nearly all phanerogamic plant-associations. They are, indeed, a *climax* group, not only as regards structure, but also as units of vegetation; and their origin and evolution are subjects for profound study.

Dr. Arber's work on the grasses approaches the subject from many points of view, any one of which would apparently supply material for an independent treatise as large as or larger than that under review; but in this work greater emphasis is laid on the morphological and anatomical aspects of grasses—subjects the author has studied for many years. It is a most interesting volume, not only to the expert, but to the lay reader as well; and it is not easy in a limited space to deal adequately with contents so varied and comprehensive.

Two chapters are devoted to cereals the seeds of which provide food for man. These include concise accounts of the more important, such as wheat, barley, rye, maize, oats, rice and sorghum, and the less important like teff, millet and ragi (korakan). Instead of being a seasonal product, as formerly, wheat is now garnered in some part of the world throughout the year, even at the equator, as in Kenya Colony. Although Dr. Arber says that the origin of the common millet, *Panicum miliaceum*, is unknown and quotes the classical work of De Candolle in suggesting the Egypt-Arabian region as its home, it is very probable that its wild prototype is represented by *Panicum callosum* from Abyssinia. The role of sorghums in tropical agriculture is briefly dealt with. The wealth of varieties brought to light during recent years, however, reveals their prime importance to the native races in Africa and India. There seems no doubt that the pearl millet is of polyphyletic origin, as the numerous races found in tropical Africa present very diverse forms in regard to habit and structure. Africa, as suggested, may have been the home of some of the cultivated rices, as it is the home of most of the sorghums and pearl millets. Numerous wild species of rice occur in that continent, and in recent years another species of rice (*Oryza glaberrima*) has been found in cultivation in Upper Guinea.

The next chapter considers briefly pasture, sugar and scent. The quest for "pastures new" has been intimately connected with the migration of races of mankind, and the search for new grasses still goes on.

Four chapters are devoted to the bamboos, and it is interesting to read that in the Far East young bamboo sprouts, 3–5 inches in diameter, are like giant *Asparagus* and similarly used as a vegetable. Indeed, various kinds of bamboo are employed in an astonishing number of ways, from whet-stones to musical instruments, and even to drain-pipes (see p. 59). The chapter (vi) dealing with the interesting phenomenon of the periodic flowering of bamboos is very ably written, and many interesting features are brought into prominence. Some species only reach the sexual reproductive phase after a prolonged juvenile period, which may find expression in a definite term of years, but may be speeded up or retarded a little according to environment. Thus large forests of bamboos are periodically annihilated. Even plagues of rats are caused by this periodic flowering of the bamboo, for it is recorded (p. 91) that in Brazil these plagues synchronise with the fruiting and dying of a species called 'taquara', which abounds in the forests, each cane bearing about a peck of edible seeds resembling rice. The total quantity is enormous, and large areas are often covered to a depth of 5–6 in. with the fallen grain.

In her chapter on the relative age of woody and herbaceous plants, Dr. Arber makes no reference to a recent classification of the Dicotyledons (Hutchinson, "Families of Flowering Plants", vol. 1, 1926), in which it has been shown that most woody plants and herbs have arisen independently, and have been evolved side by side as parallelisms, the Magnoliaceæ and Ranunculaceæ being regarded as the most primitive, and examples of parallelism rather than close relationship. No such parallelism in regard to habit is to be found in Monocotyledons. Such monocotyledonous plants as are woody or sub-woody are much advanced in other ways, the yuccas, palms, agaves, etc., being familiar examples, and the more primitive Monocotyledons are all herbs. As the grasses are predominantly herbaceous, it seems most probable, therefore, that the woody members

which occur in the Bambuseæ are the most advanced of that tribe. For there are several herbaceous members at present assigned to this tribe with more primitive flower structure than that of some of the woody genera. These are *Guaduella* and *Puellia*, with short creeping rhizomes, herbaceous culms, broad, flat, transversely veined leaves, and trimerous flowers (with three lodicules and six stamens).

In the final chapter of the series on the bamboos, a summary is given of the author's valuable researches on the so-called anomalous genera *Streptochæta* and *Anomochloa*, which have been placed in various tribes by different authorities. Two separate tribes for these two genera have recently been constituted by C. E. Hubbard (Hutchinson, "Families of Flowering Plants", vol. 2, 1934). *Streptochæta* is primitive in the possession of six stamens, a trifid style and a perianth almost equivalent to that of some Liliaceæ, and not resembling the familiar type of lodicule. *Anomochloa* is one of the most peculiar of all grass genera; in fact Dr. Arber is tempted to doubt whether it is really a member of the grass family at all. It much resembles certain Marantaceæ, whilst its floral structure is still imperfectly known, the lodicules being probably represented by a hairy ring round the stamens.

The constituent organs of the reproductive shoot have been the subject of much controversy. In her consideration of this portion of the grass plant, Dr. Arber first deals with the various types of inflorescence, leading on to its units, the spikelets. The structure of the latter often presents difficulties of interpretation owing to the reduction, modification or suppression of individual organs. The microtome technique employed by Dr. Arber and other workers has, however, in some cases assisted in solving these difficulties. The author describes all parts of the spikelet from a structural point of view, and follows it by an account of the method of flowering and seed production. Protogyny is considered to be rare in grasses, occurring in those which have no lodicules, such as pearl millet and meadow foxtail. She suggests that protogyny and lodicule suppression are interconnected, because the later emergence of the anthers is due to the difficulty of forcing the flowering scales apart, a function usually performed by the lodicules. In many genera the spikelets have been subjected to compression, causing reduction or suppression of some or all of the sexual organs, and even of some of the glumes, lemmas and paleas. A series of examples of sterilisation may be seen, commencing with *Hierochloë*, in which the lateral florets are male, and ending in *Phalaris*, in which they are reduced to rudimentary or very small lemmas. Even the branches and branchlets of an inflorescence, as in *Pennisetum* and *Setaria*, may be entirely reduced to bristles.

Several chapters deal with the vegetative morphology of the grass plant from the germination of the seed to maturity.

Chapter xv discusses the distribution and dispersal of grasses, which are found in all parts of the world, from the humid tropical forests to the regions of perpetual snow. They are formidable competitors in the struggle for existence, and are usually capable of ousting other herbaceous plants. This is due mainly to their mode of growth and their adaptability. Only two flowering plants are known to penetrate the Antarctic, and it is interesting to note that one of these is a perennial grass, *Deschampsia antarctica*. Some genera show a remarkable range in altitudinal distribution; for example, very closely related species of *Festuca* occur from sea-level up to nearly 18,000 ft. The varied conditions under which they grow are probably not equalled by any other family. Besides the aquatic grasses, some typically terrestrial species will bear long periods of submersion in water, whilst the opposite extreme is to be found in those which are capable of withstanding extreme heat and drought, such as occur in desert regions, as, for example, *Spinifex paradoxus*, one of the dominant species in the Sturt Desert of Australia, and various species of *Aristida* in the Libyan Desert. Sand-binding grasses have been of great importance to man. Their use in preventing erosion in Great Britain was realised in very early days, for an Act of Parliament in the time of Queen Elizabeth decreed it illegal for the marram grass (*Ammophila arenaria*) of our sand-dunes to be eradicated.

The reclothing of devastated areas by volcanic action is discussed by the author, who records that in the case of the island of Krakatau, doubt has been thrown on whether all plant-life was actually destroyed, and that probably some grasses in the form of their rhizomes or seeds may have survived, thus rendering the methods of their reintroduction open to question. The study of the methods of distribution of many grasses reveals some astonishing adaptations of both vegetative and reproductive organs for dispersal. Sometimes whole plants are carried considerable distances by wind or water. Besides those mentioned by Dr. Arber, it is interesting to note that at least one grass, *Stenotaphrum secundatum*, which grows along seashores in the tropics, probably owes its wide distribution to the fact that its runners and rhizomes are torn up and dispersed by the waves. In a number of cases the entire inflorescence, when ripe, disarticulates from the culm and is blown about by the wind, such as the well-known

Spinifex squarrosus, and some of the Australian 'umbrella-grasses', including species of *Digitaria* and *Chloris*. The spreading of seeds is effected in numerous ways; in many cases the parts of the spikelet bear hairs which at maturity form a spreading plume enabling the seed to be carried by the wind; in other cases, dispersal by wind agency is due to the diminutive size of the seed or to specially modified glumes and lemmas.

As the author states, unintentional conveyance by man and animals is responsible for the wide distribution of some grasses, especially those which have become serious pests in grazing land, like species of *Cenchrus* and *Tragus*, which are armed with barbed bristles.

The rather fancy title of "Pattern and Rhythm" lays stress on the homogeneity of the grass family as compared with others, and the numerous parallelisms which exist, not only between different species, but also between species in different genera, and their resemblance to other families.

Because of recent works, Dr. Arber has limited her remarks on the systematic aspects of grasses to a taxonomic table of the genera referred to in the book (p. 410), whilst ecological notes are only incidental.

Dr. Arber is to be warmly congratulated on the production of a very attractive book, in which is collected a mass of information bringing together a summary of her numerous contributions on the family. There is a wealth of illustrations, a large proportion of which are drawings of microtome sections, the value of which would have been greatly enhanced, while they would have been more easily understood by the general reader had they been always accompanied by a text-figure of the plant itself.

Ministering to Minds Diseased

Psychology and Health

By Dr. H. Banister. Pp. viii+256. (Cambridge: At the University Press, 1935.) 7*s*. 6*d*. net.

THE influence of the physical state of the body on the mental outlook has long been recognised—and a timely cathartic has often proved effective in dispelling a morbid and gloomy philosophy of life. But physical remedies are not always effective in combatting physical ills, as is witnessed by the case, treated by Dr. Banister, of a patient suffering from insomnia, who had, during seven years ordinary treatment, consumed gallons of soporific drugs without appreciable effect. Psychological treatment based on two visits of about an hour each brought about a complete cure.

It is possible that, as a class, medical men of the last generation tended to take what is termed a materialistic view of their science; it is more likely that, in medicine as in other branches of science, the supremacy of Dr. Stoffkraft was not long unchallenged. Indeed, many wise men and many wise physicians have long recognised, in health and in disease, the importance of the individual, and the controlling power of his mentality.

Surface psychology—which is anything but superficial—in its relation to the art of living is no new branch of knowledge. In unsystematised fashion, it has long been known. It may be studied daily in the lives of those around us by him who is equipped with the right sympathies and the appropriate background; it may be followed in the records of the lives of those men, obscure or famous, who have seen life steadily and seen it whole; in the pithy sayings of Poor Richard, and of other more cultivated, but not necessarily wiser aphorists. Vauvenargues, La Rochefoucauld and Pascal can teach much to him who has the germ of an understanding mind. Think of Pascal's pregnant but bitter saying, "La curiosité n'est que la vanité. Le plus souvent on ne veut savoir que pour en parler"; with the saying in mind, listen to the next debate or discussion, take note, indeed, of one's own contribution, and recognise the truth which the aphorism enshrines.

The art of living is undoubtedly an art difficult to learn or to teach, but it has been taught, albeit unsystematically; it has been learnt; and the psychologist who will read his Boswell understandingly may learn much of the art as taught by his predecessors—especially if he will resist the temptation to estimate Johnson's intelligence quotient.

But we must return to the details of Dr. Banister's valuable treatise, which is concerned mainly with the treatment of the sick by psychological means and with the helping of those who, on a superficial view, may seem to be whole, but yet are suffering from such maladjustments to their environment as may be cured by an application of that most difficult art of taking thought—and of taking thought in a very special way.

After some preliminary discussion and definitions, chapters are devoted to the problem child,

infantile sexuality and allied matters. The troubles of the healthy and of the invalid are then discussed—succeeding sections deal with suggestion, hypnosis, the unconscious and dissociation, conversion hysteria, anxiety states and compulsions and obsessions. About thirty pages are devoted to a consideration of the views of leading Continental psychologists, and the book closes with three valuable chapters devoted to methods of treatment.

Dr. Banister's book should be considered as, primarily, a laboratory manual; it contains details of many cases and of modes of treatment which should prove of great value to medical students and to general practitioners—and not of least value to him who has already, in the light of his own reason, applied psychological knowledge to his own cases; he, indeed, will welcome a co-ordinated statement of psychological truth told in plain and simple language.

It is to be hoped that, in a second edition, case-details will bulk more largely than they do in this first edition. Despite the emphasis laid and rightly laid, on the importance of the individual, it is a great encouragement to a young and untried student to find that instances exist which may help to explain some of his difficulties.

A number of students of psychologic[illegible] this interests to have been repelled by the obscure and formidable jargon of the protagonists; hence, and [illegible] last useful section of Dr. Banister's book is that which gives a succinct exposition of the theories of Freud, Janet, Jung and Adler.

Psychology has come to stay; and the book should certainly find a place on the shelves of the student of medicine—it will prove to be a very serviceable guide to those who will shortly be called to face the difficulties and decisions of a general medical practice.

A. F.

Electrons

Electrons (+ and −), Protons, Photons, Neutrons and Cosmic Rays

By Prof. Robert Andrews Millikan. Pp. x+492. (Cambridge: At the University Press, 1935.) 15*s.* net.

THE appearance of a new edition of Prof. Millikan's well-known book "The Electron" will be welcomed by the many students of physics for whom the previous edition has become a standard text. The new edition differs from its predecessor both in its title and in the addition of six chapters dealing with recent advances in atomic physics, but the first ten chapters are essentially a reprint of the second edition of "The Electron" from which, at the request of the publishers, they differ only in minor details. It is a remarkable testimony to the previous presentation of the subject matter that new chapters can be added to the existing text with no apparent hiatus in the development of the book.

The first ten chapters contain, therefore, among other matters, an account of the circumstances which led to an accurate determination of the atomic charge. Beginning with the fundamental facts of electrolysis, the author proceeds to describe the first attempt at a direct determination of the atomic charge made by Townsend, involving the use of Stokes's formula to determine the size of small drops. He discusses the adoption and improvement of Townsend's method successively by J. J. Thomson and H. A. Wilson and finally describes his own classic investigations on the value of the atomic charge and on the atomic nature of electricity.

Among other matters considered in detail in these early chapters are the Brownian movement in gases, the nature of radiant energy and the structure of the atom. Had changes in this part of the book been permitted, some reference to the Auger effect would no doubt have been made in the chapter on the mechanism of ionisation in gases, and also to the recent accurate determination of the atomic charge made in Prof. Regener's laboratory by E. Schopper, using a method based on that of Rutherford and Geiger and of Regener.

Among the six new chapters there is one on particles and waves, which treats in a simple but lucid manner particle-wave dualism in modern physics; and another on the spinning electron, with special reference to the work of Millikan and Bowen on the spectra of stripped atoms and to the new spectroscopic rules. There are admirably informative chapters dealing with fascinating topics such as the positron, the neutron, artificial transmutation and induced radioactivity.

Perhaps the least satisfactory section of the book is the chapter on the nature of the cosmic rays. In a work of this scope it would perhaps have been more useful to have given a general summary of contemporary investigations rather than to have indulged in a detailed analysis of particular investigations with which the author

has been associated, interesting and important though these are. The treatment of the subject matter appears to be directed towards establishing the hypothesis that the primary radiation is composed principally of photons, a view of its nature not generally accepted. Consequently, other investigations are treated somewhat summarily. For example, Clay's discovery of the latitude effect and Compton's organised world survey which confirmed it, receive but scanty treatment, whereas several pages are devoted to Prof. Millikan's recent surveys. No mention is made of the double-counter type of experiment introduced by Bothe and Kolhörster except in connexion with the east-west effect, of Regener's recent results with a Geiger counter in the stratosphere, or of the important observations of Kolhörster, Clay and Corlin on the penetration of the radiation into the earth and the sea. The inquiring student would be advised to supplement this chapter by reference to brief summaries of the subject such as those by Blackett and Corlin.

The book is throughout profusely illustrated, and particular mention must be made of the many beautiful expansion chamber photographs which illustrate the sections on modern atomic physics, while in spite of the somewhat dogmatic style, it is an extremely readable and lucid summary of a wide field of investigation.

The publication of a book by an authority of the standing of Prof. Millikan, whose own important researches cover a wide field, must be regarded as a notable event, and this book proves to be an important addition to the literature of atomic physics and a worthy successor to his classic work "The Electron". L. G. H. H.

The Science of Rubber ("Handbuch der Kautschukwissenschaft")

Edited by Prof. K. Memmler. Authorized English translation, edited by Dr. R. F. Dunbrook and Dr. V. N. Morris. Pp. xvi+770. (New York: Reinhold Publishing Corporation, 1934.) 15 dollars.

THE text of this publication consists of English translations of memoirs on the following scientific aspects, as distinct from the manufacturing technology, of rubber: botany, cultivation, preparation and collection (Zimmermann), chemistry (Pummerer and Koch), vulcanisation (Kindscher), chemical-analytical testing methods (Kindscher), physics (Hock), physical testing (Memmler and Schob) and microscopy of technical vulcanisates (Pohle). Edited in German by Memmler in 1930, it has now been translated and brought more up-to-date by the members of the Research Staff of the Firestone Tyre and Rubber Company under the general authorship of Dunbrook and Morris.

It is not possible in this short notice more than to touch on the general features of the publication, which is a signal addition to English rubber literature. The subject matter of the text fills 675 pages. It is well illustrated and so adequately referenced as to make it encyclopædic in its scope. The authorship of each of its sections is authoritative. The translations are smooth. Most of the sections have been amplified by the American editors, but the botanical section could have been made more complete by the inclusion of recent work on variability and propagation.

The specialist, for it is to him that the book will have appeal, will find a use for the book no less for its bibliography, its author- and subject-indexes, than for the text itself. The indexes are models of completeness. There is no such thing as difficulty in finding one's way about the publication, and we doubt if even the specialist scientific worker will find any work of major importance unrecorded. The publication represents a piece of team work of unusual merit and something all too rare in the rubber industry. Its success, despite its high price, is assured.

G. E. C.

Gardening in East Africa

A Practical Handbook by Members of the Kenya Horticultural Society and of the Kenya and Uganda Civil Services. Edited by A. J. Jex-Blake. Pp. xv+330+6 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1934.) 12*s*. 6*d*. net.

INNUMERABLE books on gardening have so ingrained it in our minds that a garden is a place in which plants from warmer climes are made to flourish in spite of our English winter, that the converse comes rather as a surprise. In this volume, the members of an English horticultural society describe their successes and failures in growing English garden-plants, with others, so near the equator as Kenya. It is a practical handbook that will be useful to gardeners in sub-tropical countries all the world round. The scientific aspects of the local horticulture are discussed in introductory chapters on climatology, soils, economic entomology and mycology, treated in a popular way, but containing a valuable body of knowledge for so young a colony as Kenya.

In a further edition more will doubtless be said about soil amœbæ, which play so important a role in most soils, and there will be need of more editorial co-ordination, for example, when the 'eel worm' has been described as a "parasitic worm" on p. 25, it should not be necessary to state on p. 310 that it is not a "vegetable", nor yet an "insect". The delightful plates are by the Misses M. Collyer and E. Napier. Lady Muriel Jex-Blake is responsible for two attractive chapters on flowering plants and shrubs and on climbing plants, while Mr. V. A. Beckley, senior agricultural chemist, has added chapters on the soil and on manuring and tillage. The foreword is by Sir Arthur Hill, director of the Royal Botanic Gardens, Kew, who has not long returned from a friendly visit to South Africa, and is well aware of the difficulties of tropical horticulture, only to be overcome by the virtue of charity in the sharing of plants and experiences.

Patterns of Culture

By Ruth Benedict. Pp. xiii+291. (London: George Routledge and Sons, Ltd., 1935.) 10*s*. 6*d*. net.

DR. RUTH BENEDICT, in a stimulating and at times provocative book, has imported the theory of relativity into the study of social anthropology, which she, like some others, regards as the whole of anthropology. She argues that in the study of cultures, European spectacles and European standards must be abandoned, and the elements of any given culture under inspection evaluated exclusively in the terms of the culture to which they belong. How this works out in actual practice is demonstrated by a study of three strongly contrasted cultures, that of the Zuñi Indians of New Mexico, of the natives of Dobu in Melanesia and the Kwakiutl of Vancouver Island. In the case of each, she shows the characteristic reaction produced by analogous circumstances in contrasting social conditions.

In demonstrating her theories, Dr. Benedict shows much originality and freshness of outlook. Her general position, however, in its stress on the relativity of cultural elements, does not in the long run get much beyond what the now much criticised 'evolutionary' anthropologist meant when he insisted upon sympathetic understanding in the study of the culture of backward peoples when construed in terms of their environments, even though he may have erred, according to the modern view, in regarding that environment as representing a stage in the development of culture.

The Struggle for Existence

By G. F. Gause. Pp. ix+163. (Baltimore, Md.: The Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1934.) 13*s*. 6*d*.

THERE is no doubt as to the interest of biologists in all questions relating to populations and the struggle for existence. The author attacks these both as an expert mathematician and as a biologist, which his work shows to be a necessary combination. In animals, the processes in the struggle are much more complicated than in plants, where certain principles seem likely to be enunciated within a few years. Population growth requires to be studied together with its limiting factors, and this is further developed in chapters relating to the competitions both between species of yeasts and between species of *Paramecium*. Then follows a study of two species one of which devours the other, the chain here being Bacteria → *Paramecium* → *Didinium*. In Nature there can be no constancy of conditions; perpetual interferences, proved to be often due to immigrations, allowing no constancy of results.

Such investigations give ideas and stimulate that spirit of inquiry that rightly appeals so strongly to the younger biologists of to-day. The price (13*s*.) is too high for the ready sale that this book deserves; the American price is 3.00 dollars, so that this is only the fair exchange rate, whereas scientific books published in England are often priced at 50 per cent more than the exchange justifies in the States, a difference that kills their sale.

Through my Telescope: Astronomy for All

By W. T. Hay. Pp. xiii+128. (London: John Murray, 1935.) 3*s*. 6*d*. net.

THIS book, as its title suggests, is chiefly concerned with observational astronomy, although a sufficient background of astronomical facts is included to enable an intelligent interest to be taken in the objects observed. There is, in fact, a surprising amount of information compressed into its small space. The main theme, however, is the pleasure to be derived from, and the scientific value of, systematic observation of heavenly bodies with moderate instrumental equipment. The illustrations are from drawings by the author, and the plates give excellent ideas as to what one may expect to see in a medium-sized telescope—being far better for this purpose than photographs, which frequently give rise to disappointment at the telescope. The final chapter gives hints as to the use of telescopes, and the whole book should be an encouragement to many to follow the author's example in becoming regular astronomical observers.

Wandlungen in den Grundlagen der Naturwissenschaft: Zwei Vorträge

Von Werner Heisenberg. Pp. 45. (Leipzig: S. Hirzel, 1935.) n.p.

THE separate publication of these two lectures, which appeared in different periodicals in 1933 and 1934, directs the attention of a wider circle of readers to the views of one of the leading physicists of the day on natural knowledge. It is not without pride that Heisenberg reviews the field already conquered by modern physics. But in all humility he does not think that these conquests have brought us any nearer to the understanding of reality, because of the mathematical character adopted by natural philosophy. Pure speculation, on the other hand, can no longer claim attention if it ignores the formal results of scientific investigation. At present, the way to know Nature should be left for everyone to find individually, unless we wish to hope that the future will provide us with a single method satisfying all points of view. T. G.

British Industries and their Organization

By Prof. G. C. Allen. Second edition. Pp. xi+338. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 10*s*. 6*d*. net.

IN the second edition of this most readable book (cf. NATURE, 133, 153; 1934) Prof. Allen extends his stocktaking of the major industries of Great Britain and their organisation to cover the years of the depression up to 1933. The statistical tables and bibliography have been brought up to date and the discussion of the far-reaching changes in economic policy during the last five years as well as of the course of Government action in the coal, the iron and steel and the cotton industries considerably enhance the value of the book to those who seek a broad view of these most important problems.

Neglect of Scientific Direction in Industry

Lessons of the Depressed Areas

IN January last a deputation representing the local sections of the Institute of Chemistry, the Chemical Society and the Society of Chemical Industry was received by Mr. C. Forbes Adams, the District Commissioner for Depressed Areas at Newcastle-upon-Tyne. Following on that meeting it was agreed to prepare memoranda on science and industry, coke, barium and other minerals, organic chemical developments and the ceramic industries, with the idea of directing attention to developments likely to lead to a permanent and progressive revival of employment in the area, and particularly to factors of fundamental importance from the technical point of view.

These memoranda have now been presented to the District Commissioner, and a further report on services to industry has yet to be completed. Together they provide a valuable commentary on the recently published first report of the Commissioner for the Special Areas*. The latter report deals with the general position of the special areas and the measures required if the problem is not to be allowed to become insoluble. The outstanding need on which it insists is that of establishing conditions whereby industry will be attracted to, instead of repelled from, these areas. It is suggested that the initial effort should come from within by the creation of local markets to be supplied by local production. To support local initial effort, Government grants to influential and widely representative development councils will be required to give them every opportunity of planning reconstruction. While this is being effected, the areas must be relieved of all excess burdens, and the special measures now being applied continued and strengthened. Resident district commissioners are essential to watch over the interests of the areas on behalf of the Government, to further local co-operation and to secure co-ordination in all fields of activity. Local efforts and the assistance possible under the Special Areas Act require supplementing by wider Government measures designed to reduce unemployment generally.

The further proposals of the general report in regard to transference out of the special areas, raising the age of entry into industry to sixteen, contributory pensions and earlier retirement from industry, shorter working hours and holidays with pay are obviously palliatives, wise in themselves but secondary to the question of finding work through the expansion of industry and creation of production. If, however, there is to be progressive industrial development in these areas, with full utilisation of their natural resources, scientific direction and research are essential. For this reason the adoption of the recommendations of the Joint Committee was urged on the District Commissioner for Durham and Tyneside.

The report on science and industry is signed by Dr. J. T. Dunn and Prof. G. R. Clemo, who, in support of the contention that the best possible scientific direction of industry is not exercised on Tyneside to-day, quote the case of a local firm which, after putting a new material on the market, found its behaviour in use was unsatisfactory. This could have been predicted if measurement of one of its fundamental physical properties had been made. The need for this was neither realised nor understood; nor, in fact, was there anyone on the staff competent to carry out the essential simple measurements. Lack of co-operation between actual business concerns in the area is another serious handicap to development, materials being bought from other areas which could as easily be, and actually are, produced in this area. As stressed in the Commissioner's report, the stimulation of local consumption of local production is a most important factor in the development of all the special areas.

Prof. Clemo and Dr. Dunn comment on the lack of progress in the area in recent times, apart from the great enterprise at Billingham, and this is reflected in the absence of local exhibits at the British Industries Fair. An even more significant pointer is found in the employment of scientific graduates in local industries. Of a total of 184 honours graduates in chemistry from Armstrong College in the fifteen years ending in 1934, only 12 (or 6·5 per cent) are known to have obtained industrial employment locally, 6 being with coal concerns, which number might have been greater had Armstrong College a Department of Fuel Technology. The situation is even worse in other pure sciences, such as physics, where only one out of 39 graduates during the last five years obtained industrial employment. In the applied sciences, although about 85 per cent of the students of electrical engineering are attached to works before entering college, only 20 per cent at most of these men are to be found holding posts locally five years

* First Report of the Commissioner for the Special Areas (England and Wales). (Cmd. 4957.) Pp. viii+106. (London: H. M. Stationery Office, 1935.) 2s. net.

after graduating. Although definite figures are not available for other provincial universities, the opinion is expressed that elsewhere the position is very different.

Replies to inquiries whether chemists from other universities have obtained posts in this area during the last five years are incomplete, but with the exception of Billingham, no such appointment is known. Further, although the record of only 166 of the 184 honours graduates in chemistry is available, it is known that 20 occupy posts in universities or technical colleges, 77 in schools, and at least 37 occupy research or administrative posts in industry elsewhere; thus indicating that the right type of man is turned out in the area.

Prof. Clemo and Dr. Dunn accordingly urge that neglect of research is one reason why the area, in spite of its great natural advantages of coal and other valuable raw materials, combined with its favourable position, is in its present sorry plight. These advantages and its position relative to the forests of Norway and Sweden should have put the area in the forefront of the rayon and paper-making industries had the opportunity been seized some forty years ago.

The north of England did extremely well during the first part of the industrial revolution, and the alkali industry, founded and carried on by men who made the best use of the science of their time, was for long a source of prosperity to the district. The greatest factor in the subsequent decline has been the narrow outlook, which failed to see that industry is based on science, and that a policy which drains the profits and leaves insufficient reserve for research and development is doomed ultimately to failure.

This is more than ever true to-day, when Britain no longer holds her privileged position of a hundred years ago, and has to meet the competition of other nations who have improved their training and are applying intensively the results of research and scientific discovery to the improvement and cheapening of their products. As evidence that the importance of industrial development has been less fully recognised in this district than in other parts of Great Britain, reference is made to the absence of chairs or laboratories established and endowed by industrialists such as are to be found at Liverpool and Manchester. There has been no such full realisation in the area that new industries have sprung from pure research undertaken from non-utilitarian ends in university institutions.

It is concluded that general prosperity in the district will be impossible without an extensive application of scientific methods to those industries which the local raw materials and situation make possible. Eight years ago, for example, the attention of the Chamber of Commerce and of the Tyneside Industrial Development Board was directed to several important new developments in coal products which were anticipated during the new decade. Several of these are now established processes—but elsewhere. Among the memoranda prepared under the guidance of the joint committee, that on coke directs attention to the desirability of an inquiry into the possibility of utilising the gas at present wasted at the coke ovens in the area, and in regard to the development of a coke for domestic purposes. The memorandum on barium stresses the need for an investigation on the possible uses of witterite. Another recommendation which indicates possibilities of development is that of the memorandum on the fishing industry, which calls for systematic investigation through the facilities at Armstrong College in regard to the working up of by-products from this industry, including the utilisation of fish liver oils. In particular, an investigation on the composition of herring oil is required.

Other memoranda on organic chemical developments suggest that a moulding industry could profitably be established in the district, although the manufacture of the actual resins and research in that should be left in the hands of the larger chemical firms of the country. Opportunities afforded to the local glass and ceramic industries are indicated, the seizing of which involves a strict scientific control of manufacturing processes, with some research work on both the improvement of existing products and the development of new lines, as well as adequate artistic guidance and the establishment of co-operation with local schools of art. Reference is also made to possibilities in the fire-proofing of timber and the preparation of sulphite pulp for paper making.

In the final section of their memorandum, Prof. Clemo and Dr. Dunn refer to the need for further endowment of Armstrong College, if it is to play its full part in restoring greatness to the area and particularly in research with a definite bearing on local industries. The technical colleges of the area cannot play their part in the development of local industry if they are hampered by lack of adequate equipment or staff. Their work is intimately related both to pure research and to the needs of industry. At one end of the scale they supply industry with young men well trained in the fundamental principles of their own branch of industry, who can therefore rapidly adjust themselves to the working conditions imposed by new discoveries; at the other end, they are teaching students to recognise and interpret their everyday work in the light of some guiding principles, with obvious gains to students and to industry.

Wallace's Line and the Distribution of Mammals

THE very definiteness of 'Wallace's Line', which threads its way with precision, though without much apparent geographical reason, between Borneo and Celebes and between the almost contiguous islands of Bali and Lombok, and so marks the boundary between the Oriental and Australian zoogeographical regions, must have raised a doubt in the mind of many a zoologist; and sometimes the doubt seems to have been justified. In an introduction to the most important analysis which has been made in recent years of the facts of mammalian distribution bearing upon the authenticity of Wallace's boundary*, Dr. W. K. Gregory cites two serious criticisms.

An examination of the fauna of the East Indian Archipelago led P. N. Van Kampen in 1909 to a very definite conclusion. "According to the researches of more recent times, among which should be mentioned especially those of Von Martens, Max Weber and the Sarasins, it becomes evident that such a sharp boundary as Wallace drew does not exist. Not only is there none where he drew it, but no such line exists anywhere in the Archipelago. Of course it is possible to draw such a line which apparently bounds the distribution of some single group; . . . But taking the fauna as a whole it is certain that no line may be drawn; but, rather, we may lay out a transition zone in which the fauna of India and that of Australia are mingled, and wherein from the west to the east the Australian components increase more and more in number; and on the other hand, the Indian tend to die out." Van Kampen regards all the transition region as being essentially linked with the eastern half of the Archipelago, that is with Wallace's "Australian" half, although he insists that even the boundaries of the transition region are not sharply defined.

More recently, W. D. Matthew (1915) proposed another solution which in effect obliterated Wallace's boundary as the Oriental-Australian divide. He created a new sub-region—Australo-Malaya—which included the islands east of the 'Line', "the debatable ground between the Oriental and the very distinct Australian region", although "the consensus of opinion classes it by preference with the Australian".

Now Henry C. Raven enters the debatable ground and, as the result of a very thorough study of the mammalian fauna, finds new support for the old 'Line'. He has some right to express an opinion, for from 1912 until 1918 he collected mammals and other vertebrates in the Dutch East Indies for the United States National Museum, and from 1921 until 1923 he carried on similar collecting in Australia for the American Museum of Natural History. Finally, he has tabulated and mapped the distribution of all the known forms of mammals in the region—2,240 species and subspecies.

The broad fact which has weighed most with critics of 'Wallace's Line' is that many creatures have broken across it in an easterly direction. Raven, therefore, analyses the list of mammals which have transgressed the supposed boundary. His tables and maps are full of suggestive information, and it amounts to this: that the mammals which have crossed in greatest numbers are the bats, shrews, true rats and mice. True squirrels crossed from Borneo to Celebes; true pigs reached New Guinea; true deer (*Cervus*) spread from Java to Celebes, but were also carried about by natives. Indeed, all the transgressions cannot be attributed to natural distribution, for man transported some of the Viverridæ, although *Paradoxurus* may have drifted over the boundary, and of other Carnivora, while one species of *Felis* reaches Sumba (not Sunba as in the text, p. 195), the dingo was man-borne. The lemur *Tarsius* and the macaques of Celebes complete the list, except for the greatest mammalian transgressor of all—man.

How does this list stand in comparison with the series of mammals which have found 'Wallace's Line' to be a real boundary? Of the East Indian forms which do not transgress the line, there are the hedgehogs (Erinaceidæ) and tree-shrews (Tupaiidæ) amongst Insectivora, the tree-shrews, with thirty-nine species, reaching Lombok and spreading along the west of the 'Line' to the Philippines; *Galeopithecus*; the Spalacidæ; the squirrels (excluding *Sciurus*), with eighty-seven species widely distributed west of the 'Line' but none crossing over; porcupines, hares and rabbits; the pangolins; amongst the Ungulates, the chevrotains (*Tragulus*) with forty-three species in the Malayan region, the muntjac deer, tapirs and rhinoceroses have all had their wanderings checked at 'Wallace's Line'. So it is with most carnivora: the dogs (other than the dingo), the single species of bear, and the Mustelidæ, of which eight genera occur in the Malayan region. Apart from the monkeys already mentioned, the Primates keep within the same limits, and they include thirty-six species of semnopitheques, fifteen species of

* Wallace's Line and the Distribution of Indo-Australian Mammals. By Henry C. Raven. *Bull. Amer. Mus. Nat. Hist.*, 78, art. iv; 1935.

Macacus, eight species of gibbons and one highly variable species of orang—all of East Asiatic origin, and none transgressing the 'Line'.

Whatever may be said about the inefficiency of the supposed boundary, it is evident that it has acted as a real barrier to far more mammals and mammalian groups than it has allowed to pass; and, in Raven's words, "this seems consistent with the fact that 'Wallace's Line' for the most part marks the eastern boundary of the ancient continent, while the islands east of it have had only occasional contacts with it. The facts suggest that those numerous families which failed to cross Wallace's Line only reached it in relatively modern times after the barrier was fully established".

Much has been done in the region since Alfred Russel Wallace published his observations and deductions in the sixties and seventies of last century, and the general run of investigation is to suggest that by narrow and temporary land bridges between deep seas, the islands of the Malay Archipelago made occasional contact with the old mainland of Cathaysia. So are explained the abundance of mammalian forms in the Malay Peninsula and Borneo, parts of the old mainland, and the relative scarcity of mammals in Celebes and the Philippine Islands, outliers of the continent. 'Wallace's Line' gains its significance and is a real boundary because it indicates the line of the continental shelf of the old mainland, and that marked the limit of distribution for most East Indian mammals. Van Kampen underestimated the significance of the 'Line', which Raven regards as being "well-established" by the distribution of mammals; this refers more especially, as Gregory points out, to the southern two-thirds of the 'Line', for the northern end, where it runs south of the Philippines, appears to mark a break of more recent formation and of less zoogeographical significance.

JAMES RITCHIE.

Royal Society of Canada

ANNUAL MEETING

THE Royal Society of Canada held its annual meeting on May 21–24 at McMaster University, Hamilton, Ontario. The presidential address by Prof. W. Lash Miller dealt with "Some Applications of the Methods of Physical Chemistry to the Study of Micro-organisms". The Flavelle Medal for 1934–35 was presented to Dr. F. T. Shutt, for his numerous contributions in the field of chemistry. The Lorne Pierce Medal was awarded to Dr. E. Montpetit, and the Tyrrell Medal to Brig.-General E. A. Cruikshank.

Prof. L. M. Gould, of Carleton College, Northfield, Minnesota, gave the annual public lecture, his subject being "Adventures in Antarctic Geology". Prof. Gould was a member of the recent Byrd expedition. His lecture was an outstanding humorous presentation of scientific facts.

In Section I (Literature française, Histoire, etc.) eighteen papers were presented, and seventeen in Section II (English Literature, History, etc.). Amongst a number of important contributions might be mentioned that of Dr. Lighthall on a newly discovered *Journal* of James and Andrew McGill. Besides supplementing greatly the hitherto scanty knowledge of James McGill, the founder of McGill University, this 522-folio-page work gives much information on the affairs of the North-West Fur Company from 1797 until 1814.

The contribution, "De l'influence de la révolution americaine dans la province de Quebec" by Gustave Lanctot, and that by L. W. Howay on "Negro Immigration into Vancouver Island in 1850", served to emphasise the ever-present problem of the influence on Canada of political changes in the United States of America.

The feature of Section III (Mathematical, Chemical and Physical Sciences), which was held under the presidency of Prof. E. F. Burton, was a symposium on supra-conductivity. Prof. Burton in his presidential address gave a summary of the general phenomena of supra-conductivity. He was followed by F. G. A. Tarr, who spoke on the magnetic effects in supra-conductors, and announced that he finds the effective permeability to be influenced by the geometrical shape of the body. A. D. Misener gave results of experiments which indicated that the transition point for thin films of lead is a function of the thickness of the film. The results of experimental work done at the cryogenic laboratory at Toronto were summarised, and this was followed by three theoretical papers on the explanation of supra-conductivity, by C. Barnes, H. Grayson Smith and Prof. L. V. King. Prof. King's theory, founded on electric polarisation and space lattices, was an important contribution; the theoretical curves for the Wiedemann-Franz relation and the effect of a magnetic field on the transition temperature

are in satisfactory agreement with experimental results.

Among the hundred and twenty-nine papers presented to the section, space permits the mention of only a few. Prof. L. V. King presented a paper on the theory of acoustical resonators in which he succeeded in obtaining an exact solution for the case of a semi-infinite cylinder bounded by an infinite flange. The agreement with Rayleigh's approximation is excellent. Dr. L. Gilchrist and his collaborators presented two papers on the results of applied geophysical work and Dr. H. G. I. Watson spoke on an improved electrical method of using the point electrode in geophysical field work. A paper by Prof. J. Satterly and J. C. Strachan on the measurement of surface tension of water and mercury by means of stationary waves on a vertical jet was the subject of an interesting theoretical discussion as a result of the values obtained for mercury by this method. Dr. Otto Maass presented a paper in collaboration with W. H. Barnes and R. S. Brown giving the results of determinations of the specific heat of liquid D_2O from 0° to 100° C. Among the several papers by Dr. O. Maass and his associates, mention may be made of an interesting investigation on the dielectric constants of propylene and methyl ether for both the liquid and vapour forms from room temperature to 10° C. above their critical temperatures. A definite difference in dielectric constant of liquid and vapour has been found to persist above the critical temperature.

Dr. J. A. Gray and J. S. Marshall presented papers on the scattering of β-rays in which the loss of energy by a homogeneous beam scattered through an angle of approximately 90° is measured and the absorption in aluminium of homogeneous β-rays determined. Further results on the study of pleochroic haloes were presented by Dr. G. H. Henderson. Evidence for instabilities resembling eddies in the striated discharge from measurements made using a small Rayleigh disc was given in a paper by Dr. D. A. Keys. Dr. G. M. Shrum gave an account of a method of finding the vitamin A content of pilchard oil from the absorption spectrum. Dr. D. C. Rose read an interesting paper summarising the results of a series of continuous records of atmospheric potential gradient, taken at Ottawa, which show a relation between weather conditions and the deviations from the average type of diurnal variations. In a paper presented by J. O. Wilhelm, A. D. Misener and A. R. Clark, the results of viscosity measurements on the two forms of liquid helium were given. Helium I at 2·3° K. has a viscosity of 0·00027 c.g.s. units and helium II at 2·2° K. has a viscosity of 0·000033 c.g.s. units, which is not very different from that of helium gas. Several papers on spectroscopy, particularly on the hyperfine structure of lines, were presented by Dr. Stanley Smith, A. B. McLay, M. F. Crawford and others.

An exceptionally interesting series of papers was presented in Section IV, and the following list of subjects discussed indicates their wide range of geological interest:

Physiology of northern British Columbia; the deformation of post-glacial lake terraces in Ontario; problems in stratigraphy in the complex series of southern Quebec; a late Cretaceous fauna of southern Alberta; a revision of the genus *Tetradium*; a revision of the genus *Calapoecia*; a discussion of Archæo-cyathinæ; the differentiation and structural history of the Sudbury Nickel Irruptive; heavy accessory minerals in granites; igneous breccias; new types of pleochroic haloes and their causes; the composition of asbestos and related fibres; rock flour glacial 'White Silts' in southern British Columbia; fabric analysis in structural petrology; and geological deductions from deep focal earthquakes.

The meeting was brought to a fitting close by an excursion to examine the interesting geological features in the vicinity of Hamilton.

Prof. John Tait in his presidential address to Section V (Biological Sciences) spoke on "Some Structural Implications of the Respiratory Mechanism in Animals", and illustrated his viewpoint with examples from a very wide range of organisms. Eighty-six papers were presented in this section; Sir Frederick Banting, Prof. C. H. Best, Prof. E. M. Walker and their respective collaborators presented work on varied endocrinological and related subjects, which included respiratory metabolism and poisons; salt secretion; the site of formation of the phosphates of blood serum; the phosphoric esters of normal and malignant tissues; the biological effects of sericite and various other mine dusts; and the respiratory metabolism of the seal. Prof. J. B. Collip and his collaborators presented work on endocrine interrelations during pregnancy; the influence of prolonged administration of an anterior pituitary extract on the ketosis of experimental diabetes; the production of endometrial moles through operation on the rat uterus during the second part of pregnancy; the nature of the constitutional factor in chronic atrophic rhinitis; and a number of other papers on the effects of various hormone extracts. Dr. J. S. L. Browne and E. M. Venning showed the effects of various treatments on normal and ovariectomised women. Prof. H. Wasteneys and his colleagues presented papers on factors affecting the rate of protein breakdown and on the synthetic action of pancreatic lipase, together with reports on new biochemical techniques. Prof. D. T. Fraser and colleagues gave an interesting

group of papers on sera and toxins. Prof. P. Masson spoke on "La multiplicité probable des syncytium de Schwann".

Papers of a general zoological or botanical nature numbered thirty-one. Prof. Marie-Victorin, J. Rousseau and J. Brunel gave the results of systematic studies of the Quebec flora. Prof. R. B. Thomson presented a new interpretation of the segmental organisation of *Osmunda* and Prof. H. S. Jackson described variations in the short-cycle rusts; with their colleagues and students they presented a series of other papers on plant anatomy and mycology. Dr. J. H. Craigie gave an exhaustive account of the epidemiology of wheat stem rust. Dr. J. W. McArthur presented data on tomatoes which are of great significance for general theories of the inheritance of quantative characters. Dr. L. O. Gaiser showed the occurrence of different chromosome numbers in various wild populations of *Liatris punctata*. Prof. A. H. R. Buller reviewed our knowledge of the sclerotia of the higher fungi. Prof. G. H. Scarth and J. Levitt described a method of measuring water permeability of freed plant protoplasts and gave new data on the problem of cell permeability in relation to hardiness.

A dinner in honour of Prof. Wilson Smith, professor of botany at McMaster University, who is retiring this year, and various field excursions were interesting features for this Section.

The social arrangements made by McMaster University and local residents, and the facilities for accommodation, exhibits and meetings provided by the splendid new buildings of the University were much appreciated.

Obituary

Prof. B. L. Robinson

FLORISTIC botany suffered a heavy loss by the death on July 27 of Benjamin Lincoln Robinson. Born at Bloomington, Illinois, on November 8, 1864, he graduated A.B. at Harvard in 1887, and then studied under de Bary at Strassburg, where he took the Ph.D. in 1889. His early work was anatomical, especially on unusual stem-anatomy; his thesis was on the stem-anatomy of *Phytocrene macrophylla*.

Returning to Harvard, Robinson became assistant in the Gray Herbarium under Sereno Watson, and on Watson's death in 1892 was appointed curator. The development of the Herbarium and the continuation of the taxonomic researches on American botany begun by Gray and continued by Watson have been Robinson's life-work. He found the Herbarium poorly housed, inadequately equipped, with a meagre endowment, and no definite status in the University. By the aid of generous donors he was able, during the years 1909–15, gradually to replace the little old building by an imposing modern structure which has been described as the safest and most conveniently arranged and best equipped herbarium building in the world. The endowment in 1899, by Mrs. Gray, of an Asa Gray professorship of systematic botany, of which Robinson was the first incumbent, added instruction to the functions of the Herbarium.

Two important pieces of work demanded attention when Robinson became curator—the completion of Gray's "Synoptical Flora of North America", and a much needed revision of Gray's "Manual of Botany". The former, with the aid of several experienced botanists, was completed in 1895–97, and the latter in conjunction with M. L. Fernald in 1908.

The results of Robinson's work and that of his assistants, on the floras of North America, Mexico and tropical South America, are embodied in a long series of papers in the *Proceedings of the American Academy of Arts and Sciences* and other periodicals. The substantial volumes of the reprints collected in the convenient form of "Contributions from the Gray Herbarium" are a monument to their industry. Robinson was specially fond of the Compositæ, and his "Revision of the genus *Brickellia*" was the first of the larger "Memoirs of the Gray Herbarium" begun in 1907.

Robinson's interest in local and regional botany found expression in the New England Botanical Club started in Boston in 1895, and for thirty years after its inception in 1899 he edited its journal, *Rhodora*. The Club collection lodged in the Gray Herbarium numbers more than 150,000 sheets.

British botanists showed their appreciation of Robinson's work by electing him to the foreign membership of the Linnean Society of London in 1922. His colleagues and friends at home and abroad will regret the passing of an eminently sane critical botanist and a courteous and kindly gentleman.

A. B. RENDLE.

WE regret to announce the following deaths:

Lieut.-Colonel H. W. Acton, C.I.E., formerly director of the School of Tropical Medicine, Calcutta, on August 23, aged fifty-two years.

Prof. Henry Briggs, O.B.E., Hood professor of mining in the University of Edinburgh since 1924, and professor of mining in Heriot-Watt College since 1919, on August 24, aged fifty-two years.

Prof. E. Jeanselme, emeritus professor in the faculty of medicine in the University of Paris, known for his work on syphilis, leprosy, and the history of medicine, aged seventy-seven years.

News and Views

Protection during Air Raids

THE recent air exercises at Portsmouth have shown once more that in some states of the weather it is impossible to prevent a hostile air fleet from launching an attack upon a city. It is essential, therefore, that we should do all we can to minimise the effects of air raids, if unfortunately it should be found impossible to prevent wars. The Government is preparing a series of six handbooks dealing with different aspects of the problem, and the first of these has recently been issued (Air Raid Precautions, Handbook No. 2. Anti-Gas Precautions and First Aid for Air Raid Casualties. Pp. 110. London: H.M. Stationery Office, 1935. 6*d*.). Mr. C. B. O. Mohr, 147 Milton Road, Cambridge, the secretary of the Cambridge Scientists' Anti-War Group, writes, however, to say that his Group considers that with the proposed protection casualties up to 30 per cent of urban populations are likely to occur. This Group is investigating the technical side of the problem, and he suggests that other scientific workers should do likewise and make their results known. These dangers can no longer be ignored, but on the other hand they should not be exaggerated. It is not only sensational journalists who have published misleading statements about new engines of war of extraordinary potency, but even statesmen in responsible positions who are in a position to obtain accurate information. One of these has said that scientific men "will turn to making a high explosive bomb about the size of a walnut and as powerful as a bomb of big dimensions". The actual fact is, however, that every endeavour has failed to produce an explosive appreciably more powerful than nitroglycerine, which was discovered by Sobrero in 1846. Equally exaggerated statements have been made about the effects of gas bombs; but high explosives, incendiary and gas projectiles are all very serious sources of danger and should be investigated authoritatively and impartially.

Academic Freedom

THE Conference on Academic Freedom held at Oxford on August 14–16 was arranged by the provisional committee formed last October following the censure passed on addresses by Mr. H. D. Dickinson, of the University of Leeds, and Prof. H. J. Laski, of the University of London. The Conference opened with a discussion on academic and professional freedom, over which Prof. J. L. Myres presided, and a standing committee was formed to give permanent character to the protest against any infringement of the rights of academic freedom. Mr. G. D. H. Cole pointed out that, although in Great Britain we are relatively immune from interference with academic and professional freedom, there is a serious danger of a rapid growth of intolerance, and this applies particularly to the professional worker in business or industry. What is wanted is not to prevent interference altogether but to keep it within the limits within which it is absolutely necessary. The difficulty arises over the exercise of the professional man's rights as a citizen and the rights he holds in common with other people in matters of personal conduct and behaviour. Bertrand Russell made a vigorous plea for freedom for teachers to express their opinions within as well as outside their professional activities, and for organised defence against victimisation.

AT the second session of the Conference, over which Prof. Lascelles Abercrombie presided, the question of international professional relief was discussed. Reports were read dealing with the persecution of teachers of all grades in Italy, Spain and Bulgaria as well as in Germany. Prof. Abercrombie said that internationalism must be identified with civilisation itself. A resolution was passed recognising the need of relief for persecuted teachers in other countries besides Germany, and establishing a committee to co-ordinate such work internationally. The final session of the Conference, over which Prof. Julian Huxley presided, dealt with the utilisation of science, and Prof. Huxley suggested that a long-range policy of the utilisation of science would involve the transformation of the economic and social system. Mr. J. L. Hodgson insisted that no creative work of value is ever done for money, and Dr. L. E. C. Hughes said that if science is to have a broadening humanitarian future and the scientific worker is to have a share of responsibility for his actions, it can only be in accordance with his own standards of scientific procedure and not with those arbitrarily imposed by non-scientific politicians. A resolution was passed to set up a committee of representatives of scientific and technical organisations to co-ordinate the activities of scientific associations and scientific workers in carrying out the pledge to secure that, so far as lay in their power, science should be used only for the benefit of humanity.

Artificial Radioactivity and Therapeutics

A NOTE in *The Times* of August 24 states that Prof. Ernest Lawrence, of the University of California, reports further progress in the production of artificial radioactivity. By subjecting ordinary salt to high-voltage X-rays, he claims to have produced in his laboratory minute amounts of radio-sodium, which emits radiation only of the γ-type, and has a half-life period of only about 15 *hours* as compared with the 1700 *years* of radium, while the suggestion is made that great therapeutic possibilities are thus opened up. The high reputation of Prof. Lawrence leaves us in no doubt as to the validity of his experimental claim; but it seems all the more necessary to suspend judgment about therapeutic possibilities until a vast

amount of experimental biological work has been carried out. It was suggested that it might be possible to inject the radio-sodium into the tissues, apparently with the view of obtaining its local action upon malignant growths. How the localisation is to be effected will, we think, be rather a problem. A further point is that the short half-life period is not necessarily by any means an advantage from the therapeutic point of view. One of the certain facts which have resulted from the scientific study of radiation therapy is that uniform and carefully adjusted dosage is essential to success. The new product—radio-sodium—produces a form of radiation which is rapidly diminishing in amount; constancy of radiation, therefore, cannot be expected. It is certainly by no means the case that an initial heavy dose of radiation which rapidly decreases will have the same biological effect as the same total dose provided by a smaller constant source acting for a longer time. From the physico-chemical point of view, Prof. Lawrence's work is of the deepest interest, but to mention therapeutic possibilities at this early stage seems to us decidedly premature.

Red Kafirs of Nuristan

IT is anticipated that further light will be thrown on the much-disputed origin of the Bashgali, or 'Red Kafirs' of Afghanistan, by recent investigations of their language and customs by Dr. George Morgenstierne, of the Göteborg High School, Sweden. In the meantime, *The Times* correspondent at Simla reports in the issue of August 17 that a German botanical expedition, which has worked its way through the Hindu Kush to the Chitral, has come into contact with the Red Kafirs among other strange tribes of Nuristan. The Red Kafirs—so-called to distinguish them from the Black Kafirs, whom some ethnologists regard as having negro affiliations—are sometimes credited with an origin which legend traces to Arabia, while on another view it has been suggested that they are descendants of the soldiers of Alexander. The most probable theory is that both racially and culturally they preserve a strain of the same stock as the Aryan invaders of India. Although they have been converted to Islam, they retain a number of pagan customs, in which some would see traces of ancient Greece. It is probable, however, that the resemblance is no more than generic, and that the strange customs reported of them are a debased survival of beliefs of the primitive Arya. Thus it is said that although they believe in one chief god, they also recognise forty or fifty other deities, to whom sacrifices are offered on high places, while the dead are placed in sacred groves. One of the most interesting features of their customs is a song and dance ritual in connexion with a central altar. Dead heroes are commemorated by wooden equestrian statues, which are sometimes accompanied by figures of an attendant and the hero's wives seated behind on chairs. The general character of these statues and their technique have been made the basis of a suggested connexion with the statues of Easter Island, and thought to point to one possible source of the 'Aryan' strain which some would see in Polynesia.

Restoration at Avebury

OPERATIONS for the exploration and restoration of the avenue leading from Overton Hill to Avebury, which were begun by Mr. Alexander Keiller last year, have been resumed. It is expected that all the surviving stones of the avenue will shortly have been placed in their original positions. The recent work has yielded information as to the original plan and method of construction additional to that obtained last year. Six stones, it is stated in a report in *The Times* of August 24, have been re-erected this year, including two of the largest megaliths known in the whole of the avenue, and the only two remaining stone-holes in the section have been identified; and at the time of writing two stones were still to receive attention. Of these, No. 9 is the only one which has never fallen. Advantage will be taken of the concreting, which will make it safe for future generations, to examine the method of packing followed when it was erected originally. The companion stone, No. 10, re-erected by Mrs. M. E. Cunnington in 1912, was shown by last year's examination to have been replaced some distance from its original position, as well as back to front and upside down. It will be placed in its correct position in its proper stone-hole, which has recently been discovered. In the next section, excavations are being undertaken on the sites of the stones between the north-western limits of last year's operations and the entrance to the circle. Here evidence has been found to show that at least two of the stone posts were broken up on the spot and without the use of fire. No. 39, partially uncovered in the laying of a pipe-line in 1913, and No. 40 have now been completely excavated, and will be re-erected shortly.

Further Discoveries at Colchester

LATER excavation of the remains of the remarkable wall discovered on the Romano-British site on Sheepen Farm at Colchester (see NATURE, August 17, p. 251) have served only to strengthen early impressions of its singular character. It has been found to run in an east-west direction for a distance of approximately 352 ft. At the eastern end, the possibility of further examination comes to an end at Sheepen Lane, so that it cannot be stated how far, if at all, it extended in this direction. At the western extremity, after a somewhat sinuous course, the wall turns in a right-angled bend to run northward, the construction continuing to be identical in form. The northern corner of what was evidently a large enclosure was located on this western side at a distance of 291 ft. from the southern turn. The course of the northern face is now being traced. Vestiges of cross walls, one running east and west, the other north and south, have been found at a point situated approximately 150 ft. east of the west wall. Of these, the former is the more substantial, its foundations having a breadth of 4 ft. 6 in., while those of the latter are only 2 ft. 6 in. wide. Further excavation showed these to be part of the walls of a Romano-Celtic temple, of which the enclosure was the *temenos*. The walls of the temple have now been completely traced (*The Times*, August 28).

Quetta Earthquake of May 31

WE have received from the Under Secretary of State for India an advance copy of a brief report on the Quetta earthquake. In the loss of human life, it ranks as one of the most destructive of all known Indian earthquakes. Its disturbed area was probably less than 300,000 square miles, while the Assam earthquake of 1897, the Kangra earthquake of 1905 and the North Bihar earthquake of 1934 were all felt over areas of between $1\frac{1}{2}$ and 2 million square miles. The epicentral area is a band about 70 miles long and 15 miles wide, running from Quetta, through Mastung, to midway between Mastung and Kalat. One of the most striking features of the earthquake was its brief duration, which was probably less than half a minute. The intensity of the shock rapidly diminished from the central area, suggesting that the focus was perhaps not more than a mile or two below the surface. In the district between Peshawar and Karachi, the alignment of the mountain ranges is abruptly broken by a marked re-entrant angle running up through Sibi to Quetta. At the apex of this angle, the rocks must be in a condition of great strain, and it is possibly the sudden yielding of the rocks under this strain that causes the numerous earthquakes in this part of Baluchistan.

Circulation of the Earth's Atmosphere

AT the International Meteorological Conference at Utrecht in September 1923, a resolution was passed that arose from a proposal of the late Prof. Exner for the calculation of coefficients of correlation between weather anomalies in distant parts of the world. This resolution was to the effect that long and homogeneous series of observations of pressure, temperature and rainfall should be published with the view of furthering the study of the general circulation of the earth's atmosphere; that a small number of stations at a mutual distance of 500–1,000 kilometres should be included, preferably stations belonging to the Réseau Mondial (a network of stations for which annual summaries are published); and that this material for publication should be collected with the aid of various meteorological institutes, the long series being taken up to the year 1920. This resolution took shape in vol. 79 of the Smithsonian Miscellaneous Collections under the title "World Weather Records", to which has been added recently a supplementary volume with the same title covering the period 1921–30, but also including some summaries of long records that were not available in time for vol. 79. The new material occupies the whole of vol. No. 90 of the same series of Miscellaneous Collections, the cost of publication being met by a grant from Mr. John A. Roebling. It is scarcely necessary to point out the advantage to students of world weather of a collection of data of this kind, which gathers together in a compact form material that is often obtainable only at great trouble and expense. It can be used by those who carry out statistical studies with the view of establishing equations for long-period forecasting on the lines developed by Sir Gilbert Walker and others, and also for the study of periodicities, while the addition of monthly sunspot and solar radiation data makes it possible to add the study of solar-terrestrial relationships. The supplementary material includes the long Edinburgh series, which goes back to 1731 for temperature and to 1770 for precipitation.

Marine Research at Port Erin

THE main work at the Marine Biological Station, Port Erin, Isle of Man, has been on the rearing of oyster larvæ up to the time that they settle as spat. The report for 1934 (No. 47), drawn up by Dr. R. J. Daniel, shows that many other researches are being carried out, but the grant-in-aid from the Development Commission has made it possible to investigate the feeding of the oyster larvæ. The zooids from certain common seaweeds have been used, and by choosing a succession of different species, zooids of one kind or another are provided throughout the summer months when the oyster larvæ are present in the water. This special research occupies Mr. J. A. Bruce and Dr. Mary Parke. Detailed investigations on the morphology, cytology and life-cycles of the brown seaweeds have been necessary, with the testing of various culture media. The results have so far been of an encouraging nature, and it is hoped to expand the scope of the work in future. Samples of local herring are still continuously examined throughout the fishing season. Lobster culture is also progressing, lobsterlings and younger stages as well as more than 3,000,000 plaice eggs and larvæ from the pond having been liberated into the sea. The scheme for research also includes work on the conditions and relations of inter-tidal life on the beach. It is satisfactory to see that a large number of visitors, especially classes from schools, have worked at the Laboratory during the year.

Problems of Forestry

THE fifteenth number of *Sylva* (published by the Edinburgh University Forestry Society, 1934–35), the annual journal of the Edinburgh University Forestry Society, fully maintains the standard which this publication has achieved. Among the professional articles may be included "Impressions of British Forestry", in which some interesting criticisms are made by H. E. Marées, and a second on "The Forests of Denmark", by N. Bang. Forestry in the Empire is represented by articles on "Forest Research in Trinidad", in which C. Swabey treats of the considerable progress made in this direction in recent years; the "Problem of Forestry in Southern Rhodesia", an article recommended to those interested in that portion of the Empire. Afforestation on the Bauchi Plateau of Northern Nigeria, by J. Dundas, and preliminary notes for a working plan of woodbush forests in South Africa, by C. C. Stapleton, are also discussed. Allusion is also made to the visit paid to West Africa in 1934 by Prof. E. P. Stebbing, during which he saw something of the forests of a number of British and French Colonies, returning home via the Sahara.

Tropical Diseases Research in Puerto Rico

THE eighth annual report of the Director of the School of Tropical Medicine of the University of Puerto Rico (under the auspices of Columbia University), recently received, summarises the work of the School during the year ending June 1934. Seminars, lectures and clinics are held weekly in the School, and the Pan-American Medical Association visited the School in March. Much research work has been done, of which an outline is given. This includes a study of tuberculosis and its occurrence in the Island, and a skin test for *Brucella* infection has been developed. In the Department of Chemistry, work on vitamin A testing of Puerto Rican food plants has been completed. In parasitology, special methods for detecting ova of *Schistosoma mansoni* have been devised, and some cases of human infection with the liver-fluke, *Fasciola hepatica*, have been detected. In mycology, infection with new species of ringworm organisms has been found, and the disease known as granuloma inguinale has been investigated. A list of the papers that have been published from the School is appended, together with details of administration and finance.

Twenty-Five Years of Philosophy

IN recognition of the Royal Silver Jubilee, movements in British philosophy during the past twenty-five years have recently been reviewed in the *Philosopher* (13, No. 3, July 1935). In 1910, Bertrand Russell and A. N. Whitehead crystallised the logistic tradition and created the analytic method. The neo-realist creed has been developed by Russell, and the great principle of emergence has taken an important place in modern philosophy, chiefly through the work of C. Lloyd Morgan. These and other systems are, however, opposed by the concept of idealism, the greatest British supporter of which is F. H. Bradley. This reaction against materialism has received much support from British thinkers. Bradley supports absolute idealism, which is closely related to the philosophy of the Hegelians such as Sir James Baillie, Viscount Haldane, etc. Idealism has also found great favour among leading men of science like Sir Arthur Eddington and Sir James Jeans. The antagonism between spiritualism and materialism is exemplified in the controversies concerning animate Nature—vitalism and mechanism. L. T. Hogben supports the latter, but opposed to his views are those of Sir J. Arthur Thomson and J. S. Haldane, who claim the independence of biology from physics. The past twenty-five years has witnessed a welcome approach of philosophy, religion and the positive sciences.

Early Books on the Hyacinth

UNDER the title "The Voorhelms of Haarlem", Mr. W. Roberts gives an interesting account of some of the Dutch bulb growers, and their literary efforts, during the eighteenth century (*J. Roy. Hort. Soc.*, 60, Part 3, pp. 199–208, May 1935). The Dutch trade in bulbs was established in the seventeenth century, upon a basis of secrecy. The "Dutch Gardener or the Complete Florist", a book by Henry Van Oosten, published in London in 1703, devoted four pages to the hyacinth and forty to the tulip, but gave away none of the precious information. The publication of "A Treatise on the Hyacinth" by George Voorhelm, in 1752, broke the tradition, and, far from ruining the Dutch trade in bulbs, laid the foundation for development to its present magnificent proportions. The volume was translated into English, French, Italian and German, though no Dutch edition was apparently needed. It was the first scientific treatise on bulb culture, but Mr. Roberts cites many more later volumes on the same subject, and also outlines, in pleasing style, the later development and fortunes of the house of Voorhelm.

Estimation of Small Percentages of Bismuth

IN view of the need for a generally agreed and reliable method of analysis for the small percentages of bismuth in copper, the Fiscal Policy Joint Committee, Brass, Copper and Nickel Silver Industries in 1933 enunciated, through a specially appointed Technical Sub-Committee, a number of analytical principles to be observed in the estimation. This has now been followed by a detailed method for the determination of quantities of bismuth of the order of 0·0002–0·005 per cent, based upon published literature on the subject, and the Secretary of the Committee, the address of which is Kings Court, 115 Colmore Row, Birmingham, invites comments from any who are interested.

Mining in South Australia

THE "Mining Review" of the Department of Mines of South Australia for the half-year ending June 30, 1934, shows that there has been considerable activity in gold mining, due, of course, to the increase in the value of the product. Thus the quantity of gold obtained in 1933 was slightly more than double that obtained in 1932, but its value was considerably more than double that obtained in the previous year, being in fact approximately in the proportion of 7 to 3. There is also included in the pamphlet a description of a motor-driven rotary drill which has been devised, owing to the difficulty of obtaining fuel and boiler water for the ordinary steam-driven rotary drill.

International Congress of Americanists

OWING to local difficulties, the twenty-sixth session of the International Congress of Americanists, which should have taken place in 1934, at Seville, was postponed; and at one time it was thought that no meeting would be possible before 1936. Arrangements, however, have been made for the Congress to open at Seville on October 12 next. A programme is being arranged by the Organising Committee, of which S. Gregorio Marañon, president of the Geographical Society, is chairman. The topics selected for discussion include the relations of the individual and the State in the early Spanish expeditions of discovery, conquest and colonisation; types of cities in Spanish America in the colonial period, and the functions of the Hispano-American municipality; social and juridical conditions of the Indians in the

Spanish colonial period: the critical study of the scientific work as regards geographical knowledge of Spanish America accomplished by the Supreme Council and the "Casa de Contratacion" of Seville; and fundamental problems in the archæology, ethnography and philology of pre-Columbian America. The subscription has been fixed at 25 pesetas. All communications relating to the Congress should be addressed to S. Jose Maria Torroya, General Secretary, calle del Leon, 21, Madrid.

An Active Sunspot

A RECENT feature of interest on the sun's disc has been a group of sunspots that appeared suddenly near the central meridian between August 19 and 20. Its growth is shown as follows, the unit of area being one millionth of the sun's hemisphere:

Date	U.T.	Area	
Aug. 19d	8h	0	Heliographic position: long. 356°; lat. 28° N.
20	8	250	
20	11	350	
21	8	700	
22	8	800	

On being observed with the Hale spectrohelioscope at the Royal Observatory, Greenwich, the group was obviously very active, especially about the following times: Aug. 20^d $13\frac{1}{2}^h$; Aug. 21^d $8\frac{1}{2}^h$ and $9\frac{1}{2}^h$–10^h; Aug. 22^d 9^h. During the time that the spots were under observation, there were also continuous minor changes, often too rapid to record in detail, but sometimes producing quite obvious changes in the configuration of the accompanying hydrogen flocculi in less than an hour. On August 21 a stream of relatively dark hydrogen continued for about two hours from $8\frac{1}{2}^h$ to descend with a radial velocity of 40–50 km./sec. behind the leader spot. About 10^h on the same day, after a portion of the flocculi had shown a sudden brightening, a narrow stream of dark hydrogen was shot upwards with a maximum velocity of 140 km./sec., but this faded in about 10 minutes. If this phenomenon had occurred at the edge of the sun, the profile aspect would doubtless have been an eruptive prominence rising to a considerable height.

The Sky in September

As an offset to the perceptibly shortening days, September provides in the latitude of the British Isles unexcelled night skies to those who search with binoculars or merely use their eyes. By the middle of the month at 21^h U.T. ($=22^h$ Summer Time), the great triangle formed by Vega, Deneb, and Altair is not far past culmination, whilst crossing the zenith obliquely to the meridian is the Milky Way—a brilliant sight when the moon does not interfere. Arcturus, nearing the north-west horizon, is balanced by Capella in the north-east, and after midnight the Pleiades, Aldebaran, and the head of Orion make the low eastern sky conspicuous. There are also other gems, such as the tiny constellation, Delphinus, the double star cluster in Perseus, and the well-known double star, β Cygni. The moon is full on September 12 at 12^h, and in this lunation becomes the 'harvest moon'. On September 7 it occults λ Sagittarii (magnitude 2·9), the disappearance of the star taking place in twilight at 19^h $29{\cdot}5^m$ and the reappearance at 20^h 35^m. Saturn is the only planet at all well placed for observation; in the middle of the month it transits about 23^h. The ring system appears about half-way open. On September 12^d 3^h, the planet is in conjunction with the moon. Venus is at inferior conjunction with the sun on September 8, when the planet passes 8° south of the sun's centre; a thin crescent may then be observed telescopically. The variability of Algol (β Persei) may be observed within about $1\frac{1}{2}$ hours before and after the following times: September 4^d $23{\cdot}6^h$, 7^d $20{\cdot}4^h$, 25^d $1{\cdot}3^h$, 27^d $22{\cdot}1^h$ and 30^d $18{\cdot}9^h$. The sun enters the sign Libra (Autumnal Equinox) on September 24^d 0^h.

Announcements

DR. MARSHALL A. HOWE has been appointed director of the New York Botanical Garden as from October 1, in succession to Dr. E. D. Merrill, who has been appointed head of the Botanical Department, Harvard University. Dr. Howe has been assistant director of the Gardens since 1923. He has made several field excursions, especially to Newfoundland and the West Indies, and is an authority on the Hepaticæ and marine Algæ of North America.

THE second International Speech Congress will be held in Brussels on September 6–8, under the presidency of Mlle. Hélène Vacaresco, permanent delegate of Roumania at the League of Nations. The subjects for discussion will be instruction in speech, results obtained by the former congress, international exchange of lectures, and French as a universal language. The fee is 20 francs. Further information can be obtained from L'Agence Joseph Dumoulin, 77–79 Boulevard Adolphe Max, Brussels.

A BOOK by Dr. F. W. Lanchester on "Relativity" will be published by Messrs. Constable and Co., Ltd., on September 5. It presents the theory of relativity and the relationships of space, time and gravitation, in language suited to those who, though not highly specialised in mathematics, wish to grasp the meaning of four-dimensional space-time.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

An assistant vocational guidance officer to the Kent Education Committee—The Director of Education, Springfield, Maidstone (Sept. 7).

An assistant agricultural organiser to the Notts Education Committee—The Director of Education, Shire Hall, Nottingham (Sept. 11).

A mechanical engineer to the Safety in Mines Research Board—The Under-Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, Millbank, London, S.W.1 (Sept. 14).

An assistant librarian in the University of Aberdeen—The Secretary (Sept. 30).

A research fellow, two junior research assistants, and three junior laboratory assistants to the Wool Industries Research Association—The Secretary, Torridon, Headingley, Leeds, 6.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Attempts to Produce Helium 3 in Quantity

WITH reference to the results published by Harnwell, Smyth and Urry[1] in which there is an apparent production of helium of atomic weight 3 in considerable quantities (10^{-5} c.c.) in a discharge run in heavy hydrogen, we should like to mention some experiments which we have made during the past year on similar lines. Our apparatus resembles that used by Rutherford and Oliphant[2], a beam of positive rays being directed on to a target containing heavy hydrogen, the positive rays being produced by an auxiliary discharge in heavy hydrogen gas. The voltage applied to the rays was about 150 k.v., the auxiliary discharge carried about 8 milliamp. and the current in the beam was of the order of 100 microamp., but probably only a small proportion of this consisted of ions of heavy hydrogen.

After running for one hour, the gas was pumped into a glass reservoir which was then sealed off and the gas analysed by the micro-method of Paneth and Peters. A number of such bombardments were made and in all cases the hydrogen contained helium and neon, the ratio of helium to neon being greater than that in ordinary air. We consider that this gas was derived from the walls of the glass cylinder used for the discharge, and that the enhanced proportion of helium is due to the fact that any glass in contact with air adsorbs and dissolves helium in preference to neon[3]. The release of this helium is facilitated by the presence of hydrogen.

Our reasons for preferring this explanation are two. First, the yield of neutrons, which should accompany the production of helium 3, was measured and found to be only equivalent at best to a source of 60 millicuries of (radon + beryllium); the helium corresponding to this yield of neutrons would not exceed 10^{-10} c.c. in the hour, while $10^{-8} - 10^{-7}$ c.c. of helium were commonly observed. Secondly, interferometric analysis of the helium spectral lines carried out by Mr. C. V. Jackson showed no sign of any extra doubling of the lines such as might be expected if any considerable proportion of the helium had a mass of only 3. For this analysis the helium + neon samples from five bombardments were united; the mixture consisted of about 1×10^{-7} c.c. neon and $3{\cdot}6 \times 10^{-7}$ c.c. helium, of which at least 90 per cent was ordinary helium of mass 4. It would not have been possible to detect less than 10 per cent of helium of mass 3 on account of the difficulty of photographing fringes with so small a quantity of gas.

A short recent communication by Smyth, Harnwell Bleakney and Lozier[4] appears to throw doubts on the interpretation of the evidence from the mass-spectrograph described in the earlier paper. They state, however, that their spectroscopic evidence for the production of helium remains entirely unexplained. We venture to suggest that their results may be explained in the same way as the very similar ones which we have obtained.

Radioactivity of Potassium

SEVERAL hypotheses have been put forward[1] to explain the extremely long life-period of potassium, which conflicts with the theories of β-decay as well as with Sargent's empirical rule. Klemperer[2], however, has shown by an investigation in detail that none of the processes suggested really exists. He concludes from his experiments that an unknown, relatively rare isotope, ${}_{19}K^{40}$, is responsible for the β-activity of potassium, and similarly an unknown isotope ${}_{37}Rb^{86}$ in the case of rubidium.

On general principles, it can be said that β-decay will be possible, if the difference in the energies of the initial and final nucleus, ΔE, fits the relation:

$$(1) \qquad \Delta E > (m + m').c^2,$$

where m, m' are the masses of the two particles involved in the process. Hence, in the case of ${}_{19}K^{40}$, one would expect both positive and negative electrons leaving the nucleus, due to the processes

$$(2) \quad {}_{19}K^{40} \rightarrow {}_{20}Ca^{40} + e^- \text{ or } (2a)\ {}_{19}K^{40} \rightarrow {}_{18}A^{40} + e^+.$$

Both ${}_{20}Ca^{40}$ and ${}_{18}A^{40}$ are well-known, stable nuclei; and ${}_{18}A^{40}$ is relatively the most frequent isotope of argon. This means that the binding energy of the nucleus ${}_{18}A^{40}$ must be sufficiently low, and the relation (1) would scarcely be violated for the process (2*a*), if it is valid for the process (2).

Experiments hitherto have not shown any proof of an emission of positrons from potassium. I have also tested the radiation of potassium in a cloud-chamber, without finding any track of positively-charged particles. My experiments will be continued, and the results published in the *Zeitschrift für Physik*, but it does not seem to be very probable that any β^+-emission will be found.

On the other hand, a simple β-decay of ${}_{19}K^{41}$ cannot be expected. The final product of this process, ${}_{20}Ca^{41}$, does not accord with our general knowledge of the system of stable isotopes[3]. Besides, the decay constant for this process would be lowered by a factor

of about 100 compared with the decay process of the rare isotope $_{19}K^{40}$, and the disagreement would be still more emphasised. We know further that an isotope $_{19}K^{42}$ cannot be responsible for the natural β-activity of potassium, for this isotope was produced artificially by Hevesy[4] and its half-period found to be about 16 hours. Therefore one comes to the conclusion that another relatively rare isotope of potassium exists, which is the source of the β-particles. This can only be $_{19}K^{43}$, which is transformed by the decay process to the well-known isotope $_{20}Ca^{43}$. This seems to be the only assumption not in conflict with all the available experimental evidence.

Spectroscopy of an Enzyme Reaction

IF a suitable amount of monoethyl-hydrogen peroxide is added to an active preparation of liver catalase at *p*H 7, the enzyme spectrum disappears instantly, and two new absorption bands in the green range of the spectrum appear. In the course of a few minutes, at room temperature, the new absorption bands decrease in intensity, and simultaneously the original enzyme spectrum reappears. When the change is complete, the cycle may be repeated by the addition of fresh substrate. The time required for the reaction cycle at 4° is four times that required at 24°. The reappearance of the enzyme spectrum is accompanied by the disappearance of the titratable peroxide oxygen from the system. No gas is evolved in this reaction. Acetaldehyde and ethyl alcohol are among the most probable reaction products.

The spectrum of the intermediate compound is to be attributed to a combination of the enzyme with the substrate. The alternative explanation that one is dealing here with the reduced (ferrous-) form of catalase can be discarded because neither molecular oxygen nor ferricyanide reoxidise it to the original ferric form, and because it does not combine with carbon monoxide.

Enzyme spectrum (after K. Zeile[1]):

I. 650 . . . 646–620 (629) . . . 610; II. 550–530 (540) . . . 520 . . .

510–490 mμ. (500)

Spectrum of the enzyme-substrate compound:

I. 576–564 (570); II. 540–529 mμ. (534·5)

5×10^5 molecules of the substituted peroxide per enzyme molecule are required to complete the transformation into the intermediate compound. It is interesting to note that according to J. B. S. Haldane's calculations[2], based on Zeile's and Euler's data, $1{\cdot}9 \times 10^5$ molecules of hydrogen peroxide are destroyed by one molecule of liver catalase per second under optimal conditions. This coincidence is still more striking since the enzyme is at least 5,000 times more active towards hydrogen peroxide than towards ethyl-hydrogen peroxide.

With hydrogen peroxide as a substrate, no apparent change of the enzyme spectrum is observed. The inference is, that since the rate of formation and the stoichiometry of the two enzyme-substrate complexes seem to be similar, the different catalytic efficiency towards the two substrates is due to the different velocity constants of the breakdown of the intermediate compounds.

A non-enzymatic model of the present observation is found in the reaction of methæmoglobin with hydrogen peroxide (Kobert[3], Haurowitz[4]) and with monoethyl-hydrogen peroxide. Here the intermediate compounds are similar to that observed above, so far as the absorption spectrum is concerned. But one molecule of methæmoglobin will only break up $3{\cdot}6 \times 10^{-2}$ molecules of hydrogen peroxide per second (cf. K. G. Stern[5]), and an excess of only 20 molecules of hydrogen peroxide (Haurowitz, l.c.) and of 8 molecules of monoethyl-hydrogen peroxide will suffice to transform completely the spectrum of this catalyst into that of the intermediate compounds.

Pleochroism of Crystals of Rare-Earth Salts as Evidence of the Non-Rotation of Certain Electronic Orbits

So long ago as 1888, H. Becquerel[1] recorded that the absorption spectrum afforded by crystals of 'didymium' salts was different for different vibration planes of the incident light. Later, M. H. Dufet[2] made a detailed study of the crystallographic and optical properties of neodymium, praseodymium and samarium sulphates, in the course of which he confirmed and extended Becquerel's observations by recording the wave-lengths of bands in the absorption spectra of these salts for light vibrating parallel to the acute bisectrix, obtuse bisectrix and optic binormal respectively. He found that the intensity of individual absorption bands was often, though not invariably, different for the three principal vibration planes, even to the extent of their being absent from one of them.

In the course of a study of the relationship between the optical properties and chemical constitution of certain absorbing crystals by means of a grating microspectrograph used in conjunction with a polarising microscope[3], I have had occasion to examine the absorption spectra for various vibration directions in crystals of neodymium, praseodymium and samarium sulphates, and in ceric ammonium sulphate. The method adopted was to project a conoscopic ('directions') image of the crystal on the slit of the microspectrograph by means of a Bertrand lens, using a polariser but no analyser, and ensuring that the slit and the vibration plane of the polariser were parallel to a principal vibration plane of the crystal. An oil-immersion objective of $N.A. = 1{\cdot}30$, in conjunction with an oil-immersion condenser, was used.

In this way it was possible to obtain absorption spectra which showed the effect of varying the ray

Radioactivity of Potassium

SEVERAL hypotheses have been put forward[1] to explain the extremely long life-period of potassium, which conflicts with the theories of β-decay as well as with Sargent's empirical rule. Klemperer[2], however, has shown by an investigation in detail that none of the processes suggested really exists. He concludes from his experiments that an unknown, relatively rare isotope, ${}_{19}K^{40}$, is responsible for the β-activity of potassium, and similarly an unknown isotope ${}_{37}Rb^{86}$ in the case of rubidium.

On general principles, it can be said that β-decay will be possible, if the difference in the energies of the initial and final nucleus, $\triangle E$, fits the relation:

$$(1) \qquad \triangle E > (m + m').c^2,$$

where m, m' are the masses of the two particles involved in the process. Hence, in the case of ${}_{19}K^{40}$, one would expect both positive and negative electrons leaving the nucleus, due to the processes

$$(2) \quad {}_{19}K^{40} \rightarrow {}_{20}Ca^{40} + e^- \text{ or } (2a)\ {}_{19}K^{40} \rightarrow {}_{18}A^{40} + e^+.$$

Both ${}_{20}Ca^{40}$ and ${}_{18}A^{40}$ are well-known, stable nuclei; and ${}_{18}A^{40}$ is relatively the most frequent isotope of argon. This means that the binding energy of the nucleus ${}_{18}A^{40}$ must be sufficiently low, and the relation (1) would scarcely be violated for the process (2*a*), if it is valid for the process (2).

Experiments hitherto have not shown any proof of an emission of positrons from potassium. I have also tested the radiation of potassium in a cloud-chamber, without finding any track of positively-charged particles. My experiments will be continued, and the results published in the *Zeitschrift für Physik*, but it does not seem to be very probable that any β+-emission will be found.

On the other hand, a simple β-decay of ${}_{19}K^{41}$ cannot be expected. The final product of this process, ${}_{20}Ca^{41}$, does not accord with our general knowledge of the system of stable isotopes[3]. Besides, the decay constant for this process would be lowered by a factor

of about 100 compared with the decay process of the rare isotope $_{19}K^{40}$, and the disagreement would be still more emphasised. We know further that an isotope $_{19}K^{42}$ cannot be responsible for the natural β-activity of potassium, for this isotope was produced artificially by Hevesy[4] and its half-period found to be about 16 hours. Therefore one comes to the conclusion that another relatively rare isotope of potassium exists, which is the source of the β-particles. This can only be $_{19}K^{43}$, which is transformed by the decay process to the well-known isotope $_{20}Ca^{43}$. This seems to be the only assumption not in conflict with all the available experimental evidence.

Spectroscopy of an Enzyme Reaction

IF a suitable amount of monoethyl-hydrogen peroxide is added to an active preparation of liver catalase at *p*H 7, the enzyme spectrum disappears instantly, and two new absorption bands in the green range of the spectrum appear. In the course of a few minutes, at room temperature, the new absorption bands decrease in intensity, and simultaneously the original enzyme spectrum reappears. When the change is complete, the cycle may be repeated by the addition of fresh substrate. The time required for the reaction cycle at 4° is four times that required at 24°. The reappearance of the enzyme spectrum is accompanied by the disappearance of the titratable peroxide oxygen from the system. No gas is evolved in this reaction. Acetaldehyde and ethyl alcohol are among the most probable reaction products.

The spectrum of the intermediate compound is to be attributed to a combination of the enzyme with the substrate. The alternative explanation that one is dealing here with the reduced (ferrous-) form of catalase can be discarded because neither molecular oxygen nor ferricyanide reoxidise it to the original ferric form, and because it does not combine with carbon monoxide.

Enzyme spectrum (after K. Zeile[1]):

I. 650 . . . 646–620 (629) . . . 610; II. 550–530 (540) . . . 520 . . .

510–490 mμ. (500)

Spectrum of the enzyme-substrate compound:

I. 576–564 (570); II. 540–529 mμ. (534·5)

5 × 10^5 molecules of the substituted peroxide per enzyme molecule are required to complete the transformation into the intermediate compound. It is interesting to note that according to J. B. S. Haldane's calculations[2], based on Zeile's and Euler's data, 1·9 × 10^5 molecules of hydrogen peroxide are destroyed by one molecule of liver catalase per second under optimal conditions. This coincidence is still more striking since the enzyme is at least 5,000 times more active towards hydrogen peroxide than towards ethyl-hydrogen peroxide.

With hydrogen peroxide as a substrate, no apparent change of the enzyme spectrum is observed. The inference is, that since the rate of formation and the stoichiometry of the two enzyme-substrate complexes seem to be similar, the different catalytic efficiency towards the two substrates is due to the different velocity constants of the breakdown of the intermediate compounds.

A non-enzymatic model of the present observation is found in the reaction of methæmoglobin with hydrogen peroxide (Kobert[3], Haurowitz[4]) and with monoethyl-hydrogen peroxide. Here the intermediate compounds are similar to that observed above, so far as the absorption spectrum is concerned. But one molecule of methæmoglobin will only break up 3·6 × 10^{-2} molecules of hydrogen peroxide per second (cf. K. G. Stern[5]), and an excess of only 20 molecules of hydrogen peroxide (Haurowitz, l.c.) and of 8 molecules of monoethyl-hydrogen peroxide will suffice to transform completely the spectrum of this catalyst into that of the intermediate compounds.

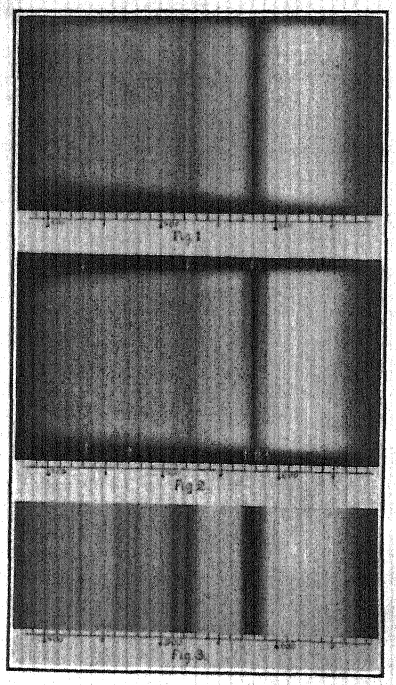
Pleochroism of Crystals of Rare-Earth Salts as Evidence of the Non-Rotation of Certain Electronic Orbits

So long ago as 1888, H. Becquerel[1] recorded that the absorption spectrum afforded by crystals of 'didymium' salts was different for different vibration planes of the incident light. Later, M. H. Dufet[2] made a detailed study of the crystallographic and optical properties of neodymium, praseodymium and samarium sulphates, in the course of which he confirmed and extended Becquerel's observations by recording the wave-lengths of bands in the absorption spectra of these salts for light vibrating parallel to the acute bisectrix, obtuse bisectrix and optic binormal respectively. He found that the intensity of individual absorption bands was often, though not invariably, different for the three principal vibration planes, even to the extent of their being absent from one of them.

In the course of a study of the relationship between the optical properties and chemical constitution of certain absorbing crystals by means of a grating microspectrograph used in conjunction with a polarising microscope[3], I have had occasion to examine the absorption spectra for various vibration directions in crystals of neodymium, praseodymium and samarium sulphates, and in ceric ammonium sulphate. The method adopted was to project a conoscopic ('directions') image of the crystal on the slit of the microspectrograph by means of a Bertrand lens, using a polariser but no analyser, and ensuring that the slit and the vibration plane of the polariser were parallel to a principal vibration plane of the crystal. An oil-immersion objective of $N.A. = 1·30$, in conjunction with an oil-immersion condenser, was used.

In this way it was possible to obtain absorption spectra which showed the effect of varying the ray

direction on the absorption bands. The results now obtained are exemplified by the absorption spectra here reproduced of crystals of neodymium sulphate. In Fig. 1 the slit and plane of vibration are parallel to the plane of the optic axes. In Fig. 2 they are perpendicular to this plane. By way of comparison the absorption spectrum of an aqueous solution of the salt is given in Fig. 3. The relations between



FIGS. 1-3.

the ordinates of Figs. 1 and 2 and the ray direction are shown in stereographic projection in Figs. 4 and 5 respectively, in which the plane of vibration is parallel to the slit.

Fig. 1 shows that there is no marked change in the absorption spectrum on passing from vibration directions parallel to Z to those about half way between Z and X, but Fig. 2 shows that some

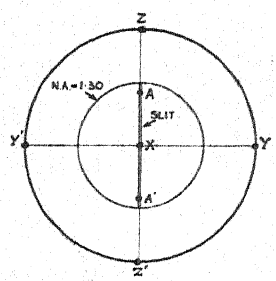


FIG. 4.

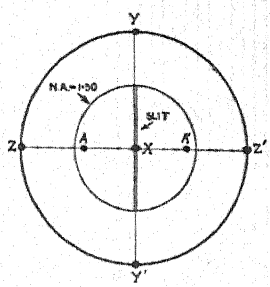

FIG. 5.

absorption bands show marked change on passing from vibration directions parallel to Y to those intermediate between Y and X. What is particularly important is that the bands fade out at different points, and that the directions for minimum absorption do not correspond with an axis of the Fresnel wave surface. In all, eleven crystals of neodymium sulphate were examined, but they all gave the same result. The positions of the bands agree, [illegible] They [illegible]ce for principal optical planes with those recorded by Dufet, with the exception that the present spectrograms do not show the bands from 622·5 to 638·0 mμ which he has described. Praseodymium sulphate behaved in an exactly analogous manner. A discussion of this, and of the results obtained with other absorbing crystals, will be published later.

It has been shown that the absorption bands of rare-earth salts are due to the incomplete N shell of electrons ($4F$ orbits), and as the present work shows that light of certain wave-lengths is not absorbed when its plane of vibration is in certain specific directions, it seems reasonable to assume that the orbits of at least some of the N electrons are fixed in relation to the crystal structure. As these are not valency electrons, it is probable that the metal ions as a whole are not capable of free rotation in the crystals examined.

I am indebted to Sir William Pope for a gift of rare-earth salts, and to Prof. J. R. Partington for the interest he has taken in this work.

Diamagnetism of Thallium Single Crystals

WHILE several investigators have determined the susceptibilities of polycrystalline metals, measurements on single crystals have been rather few[1]. Bismuth crystals have been prepared and studied with great care by Focke[2], while single crystals of a few other metals like zinc, tin and antimony have been examined by McLennan and his collaborators[3]. We have recently succeeded in making measurements of the diamagnetism of single crystals of some metals; and the results obtained with thallium are of particular interest.

Single crystals of this element were prepared by the method of slow cooling in a manner similar to that of McLennan[3]. They were investigated with a magnetic balance specially devised for the purpose, wherein the Gouy force on the cylindrical specimen was compensated electrodynamically. Measurements could be made rapidly and to within 0·5 per cent at laboratory temperatures.

It is well known that thallium crystallises in the close packed hexagonal system, the ratio c/a being 1·62. As the crystal is heated, it passes into the cubical system at 235° C. Our experiments show that, at the laboratory temperature (30° C.), the diamagnetic susceptibility parallel to the hexagonal axis ($\chi_{\parallel}$) is 0·407 (all values of χ are given in 10^{-6} units) and the value perpendicular to it ($\chi_{\perp}$) is 0·163. This gives a magnetic anisotropy of 2·50, which is larger than the corresponding values of other similar metals. The average value for polycrystalline thallium works out at 0·244, which is almost identical with Honda's value[1] of 0·24.

On heating the crystal, we find that the susceptibilities in the two directions remain constant up to 235° C. At this temperature, the mean value decreases suddenly to 0·170 and remains the same for all orientations of the crystal in the magnetic field. It is interesting to observe that while $\chi_{\perp}$ con[illegible]mains nearly the same, it is the susceptibility

value in the other direction that shows a large fall, indicating probably that the movements of atoms when the close packed hexagonal type is changed into the face-centred cubical type are predominantly in this direction. On melting the crystal at 302° C., the diamagnetic susceptibility shows a still further decrease, reaching a value of 0·153 in the liquid state.

The chemical properties of thallium indicate that it is both trivalent and monovalent. The hexagonal structure is obviously due to the three valency electrons ($6s$ and $6p$) operating in the crystal binding, while in the cubic structure, only the single valency electron ($6p$) is active. It is surprising that in both cases the metal is diamagnetic and the diamagnetic susceptibility is independent of temperature in the temperature ranges concerned.

The plausible explanation seems to be that in the hexagonal structure, the electron binding is partly homopolar and partly metallic; while only the latter type of binding is prevalent in the cubical structure.

It is interesting to note that, while the atomic diamagnetic susceptibility of thallium is 34·75 according to these measurements, the susceptibility of the monovalent thallium ion (Tl^{+1}) is 38·75, after Kido[4]. This would lead to the conclusion that the single valency electron contributes a paramagnetic susceptibility of + 4 per gram atom, a value which is of the same order as those obtained for copper, silver and gold[5].

Experiments with single crystals of other metals are in progress and the results will be published shortly elsewhere.

Measurement of the Elastic Constant of Isotropic Transparent Solids

ULTRA-SONIC waves in liquids or transparent solids may be demonstrated visually by a method developed by the author and his co-workers[1]. Ultra-sonic waves produce a regular (sinuous) distribution of density, which gives optically an effect similar to a large number of cylindrical lenses. A parallel beam of light passing normal to the direction of the ultra-sound converges therefore to a system of focal lines. The distance of two succeeding lines produced by stationary waves is equal to half an ultra-sonic wave-length; in the case of progressive waves, which must be observed by means of a high-frequency stroboscope, the distance equals one wave-length.

By measuring the distance of a great number of focal lines it has been possible to obtain the values of ultra-sonic velocities in liquids with very high precision[1]. Measuring ultra-sonic velocity in glass, I have sometimes used polarised light. On one occasion, K. H. Hoesch and I made an unexpected observation. If the electric vector of the polarised light entering an oscillating cube of glass was normal to the front of the ultra-sonic waves, we observed by means of a second nicol—crossed to the polariser—a system of lines similar to that observed in natural light; or in polarised light the electric vector of which had an angle of about 45° with the wave front, but with smaller separation. As the system of narrow lines could not be observed in natural light, I concluded that it could not have been produced by a longitudinal wave, but only by a transverse wave. That the nodal lines of the transverse wave may be seen by means of two crossed nicols is due to double refraction in the position of maximal elastic strain, just as in an old experiment by Tyndall.

Measurements of the higher harmonics of a longitudinally oscillating piezo-electric quartz crystal have proved that the higher harmonics have no anharmonic deviations between each other, but a pronounced deviation from the fundamental. This seems to indicate that the velocity of longitudinal waves tends towards a limit. As the wave-length for the high harmonics is small compared to the thickness of the quartz, it is natural to assume that this limit is given by the velocity in the medium extending indefinitely in all directions. I therefore assumed (1) that the narrow lines observed were produced by transverse waves in the glass, the other lines by compressional waves; and (2) that for both waves the formulæ for the velocity in a homogeneous isotropic medium extending indefinitely in all directions would be valid with a very good approximation, because the wave-length was very small compared to the thickness of the glass.

This hypothesis made it possible to calculate the elastic constants of the glass from the measurements of the separations of the observed lines and the frequency of the oscillations. At the high frequencies used—for example, 4,894 k.c.—one gets the adiabatic elastic constants, which are slightly higher than the isothermal. For glass which had an isothermal Young's modulus of 7,471 kgm. mm.$^{-2}$, the adiabatic modulus was found to be 7,531 kgm. mm.$^{-2}$. The agreement is too good to be accidental. Poisson's ratio was 0·2072 and the modulus of rigidity = 3,119 kgm. mm.$^{-2}$. Measurements on cubes and bars of other kinds of glass have also given very satisfactory results.

The values given above are only the results of preliminary measurements; their precision is therefore not much better than 1 per cent. It is possible, however, to get a precision of better than 1 in 1,000; Poisson's ratio may even be measured to about 1 in 10,000, a precision never obtained before.

The method is now being applied to the study of high-frequency oscillations of cubes and bars of glass, and an account of the investigation will be given elsewhere.

A New Wave Characteristic of Deep-focus Earthquakes

A PROMINENT phase appearing a few minutes after *ScS* on the seismograms at the Dominion Observatory, Wellington, of seven deep-focus earthquakes in the south-west Pacific, has been identified as a transverse wave reaching the station after having been reflected, first at the earth's surface near the epicentre, and then at the boundary of the core.

The designation of such a phase in accordance with current nomenclature would be *sScS*. This phase does not appear to have been recorded on any previous occasions. It is similar in character to *ScS*, and both are remarkably prominent on some of the seismograms.

The time-interval (*sScS–ScS*) provides a comparatively accurate method for determining the focal depths of abnormally deep earthquakes from a single seismogram at short epicentral distances : the interval being practically independent of epicentral distance.

The Oblong Sunfish (*Ranzania*) in the Indian Ocean

DR. E. W. GUDGER, of the American Museum of Natural History, recently referred in NATURE (April 6, 1935, p. 548) to the occurrence of *Ranzania* in the Indian Ocean, his only record being based on an original painting from Mauritius by Nicholas Pike.

The Australian Museum possesses two specimens of the oblong sunfish from the Indian Ocean : (1) a small example from Mauritius, of which I have published a sketch[1], and (2) a larger specimen from near Albany, Western Australia, whence the species had been recorded by McCulloch in 1910. Other records of this fish have been tabulated by me[2] in an account of its synonymy.

Apart from the few recorded specimens from Mauritius and Western Australia, there are few references to this fish in the Indian Ocean region. Thus Pennant in 1798 listed "*Balistes truncatus*" from Ceylon and this, like the sunfish in Day's Supplement to his "Fishes of India", may have been a *Ranzania*. Also in 1798, Lacépède described a *Ranzania* from a drawing by Commerson, who probably painted it in Mauritius. Dr. J. Pearson published a note and a photograph of a sunfish (Pearson, *Spolia Zeylanica*, **7**, 208 and fig. ; 1911) from near Jaffna, Ceylon, which is easily recognisable as a *Ranzania*.

Dr. Gudger has requested me to direct attention to these records, bibliographical references to which will be found in the papers quoted.

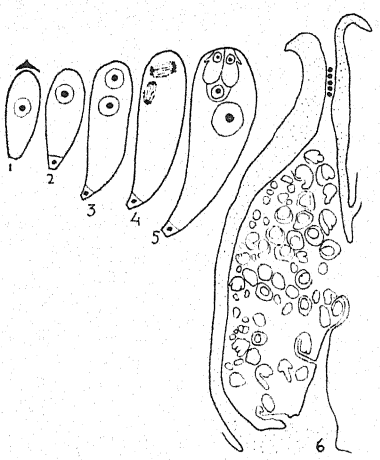
Life-History of *Butomopsis lanceolata*, Kunth.

MEMBERS of the family *Butomaceae* have received little attention, although several genera and species of the closely allied family *Alismaceae* have been thoroughly worked out. Recently I had an opportunity of investigating the life-history of *Butomopsis lanceolata*, material of which was kindly supplied to me by Mr. A. C. Joshi of Benares.

The development of the male gametophyte follows the normal course. There are two definite male cells and a tube nucleus in the mature pollen grain.

The development of the female gametophyte presents some interesting and unusual features. The hypodermal megaspore mother-cell divides to form a small ephemeral cell at the top and a larger cell below, which develops into the embryo-sac (Fig. 1). Of the two nuclei resulting from the first division, the primary chalazal nucleus is very small, and may sometimes be cut off by a wall (Fig. 2). It degenerates very early and may be said to represent the single antipodal cell the remains of which can be seen up to the time of fertilisation. The primary micropylar nucleus divides twice and produces four nuclei, three of which organise into a normal egg-apparatus and the fourth is the upper polar nucleus (Figs. 3–5) ; the lower polar is missing.

Double fertilisation occurs. The endosperm is of the Helobiales type, as also reported for *Echinodorus macrophyllus* by Dahlgren[1]. Sometimes supernumerary bodies resembling the sperm nuclei have also been seen in the pollen tube. These are similar to the X-bodies described by Artschwager[2] for the sugar beet.



FIGS. 1–5. Schematic representation of the development of the embryo-sac of *B. lanceolata*. FIG. 6, longitudinal section of the ovary, showing pollen grains in the stylar canal.

A very striking phenomenon was observed in connexion with pollination. Usually the pollen grains germinate on the stigma, but in some favourable preparations a few were found *inside the hollow stylar canal* (Fig. 6), *and even inside the ovary*. In one case a pollen grain had germinated and sent out a small pollen tube.

I am not aware if a parallel case has been reported for any other angiosperm, and would be grateful to other botanists for directing my attention to the relevant literature on this subject.

I am deeply indebted to Dr. P. Maheshwari for his kind help and valuable suggestions.

Functions of the Corpus Allatum of Insects

IT was suggested recently[1] that the active substance (moulting hormone) which initiates cell division in the epidermis of *Rhodnius* and so induces moulting, and the substance (inhibitory hormone) which restrains 'metamorphosis' until this insect is full-grown, are both secreted by the corpus allatum. By transplanting the corpus allatum from a younger

insect (4th instar) into an older one (5th instar), which then develops into a nymph instead of an adult, it has since been proved that the absence of metamorphosis in the young stages is certainly dependent on the secretion of this gland; though it is still uncertain whether there are really two hormones or only a single one in different concentrations. Further, both moulting and inhibitory effects are non-specific: both can be produced in *Rhodnius* by appropriate secretions from bugs of the allied genus *Triatoma*.

The corpus allatum remains active in the adult *Rhodnius*; this suggests that in this stage it is concerned in the regulation of reproduction. This has been proved to be the case. Adult females deprived of the brain and corpus allatum do not develop eggs; but if the brain is removed without the corpus allatum, eggs are developed normally; and the blood from females *with* a corpus allatum will induce egg development in females *without*. This effect, also, is non-specific.

The moulting hormone will not induce egg-formation; nor will the egg-forming hormone induce moulting. This little gland therefore secretes at least two and possibly three hormones regulating growth. It has already been suggested that diapause in insects may be due to a temporary failure of its secretion[1]; perhaps the so-called 'gonotrophic dissociation' (the failure to develop eggs after feeding), which occurs in the females of certain mosquitoes during hibernation, is due to the same cause. This question is being investigated.

Plankton Production and the Nitrate Nitrogen and Phosphate Cycles in the Pacific Ocean off New South Wales

RECENT quantitative research into the production of plankton and more especially into the seasonal cycle of plankton production has been accompanied by a keen appreciation of more accurate chemical analyses of sea-water. Whilst the complexity of the interrelationships between the biological and the physico-chemical conditions in the sea are being thoroughly realised, some rather definite and interesting correlations have been already demonstrated, and the investigation of the different seas in different latitudes promises further light on this subject.

One of the most interesting of these correlations is the marked cycle in the amount of nitrate nitrogen and phosphate in European seas, which seems closely bound up with the cycle of plankton production. Thus Harvey and Atkins working at Plymouth have shown how the nitrate nitrogen and phosphate are reduced almost to zero in the surface waters of the English Channel during the summer months, the fall beginning after the attainment of a maximum in the growth of diatoms during the spring.

During the past four years, a continuous series of plankton and physico-chemical determinations have been made by us in the Pacific Ocean off the New South Wales coast on the open continental shelf. The results indicate that whilst there is not such a marked cycle as in the English Channel (our sea temperatures are much higher, ranging from approximately 16° C. to 22·5° C.) there are definite occasions in the year when the nitrate nitrogen in particular and the phosphate to a slightly lesser extent are reduced to a mere trace in the surface waters, or even to zero. These occasions always occur after the attainment of a spring maximum in diatom production. The summer is a period with a low concentration of nitrate nitrogen, but the phosphate concentration typical of these seas is quickly regenerated. The winter concentration of phosphate in our surface waters ranges from 20 mgm. to 30 mgm. P_2O_5 per cubic metre, whilst the nitrate nitrogen ranges from 20 mgm. to 35 mgm. per cubic metre.

These are probably the first records from the southern hemisphere of a cycle resembling that of European seas, the only other seasonal records being those from the Antarctic with their own peculiarities.

Full details have been drawn up for publication in the *Journal of the Linnean Society of New South Wales*.

Ventilation and Domestic Heating

THE "Writer of the Note" on this subject[1] refers to experiments carried out by the Department of Scientific and Industrial Research and the Medical Research Council, and adds that "No evidence was obtained that any difference on 'nose opening' is due to the temperature of the source, either bright or dull". These experiments were carried out by Messrs. Dufton and Bedford, who received grants from the above bodies, which as customary allowed their grantees to publish their researches on their responsibility and not on that of the Department or Council.

I myself have received a grant from the Medical Research Council to aid me in research which negatives the conclusions of Dufton and Bedford.

The correctness of my conclusions about 'nose opening' rays has been confirmed not only by myself, but also by Dr. W. A. R. Thomson, who carried out observations on 100 sailors at H.M.S. *Excellent*, and by Dr. Dishoeck of the Rhinological Department, Groningen University. The latter has used an exact method of experiment, and has pointed out the cause of the failure of Dufton and Bedford to confirm my work.

Dr. Dishoeck's paper was published in the June number of the *Journal of Industrial Hygiene*. In the *Lancet*, July 13, 1935, I published the latest of my papers on the subject, and described therein a method of measuring the air-way of the nose, which should prove of general use to rhinologists. There is no doubt of the susceptibility of certain people—not all, but about 50 per cent—to 'nose opening' rays or of the importance to comfort of the quality of the rays imparted by sources of heat.

LEONARD HILL.

[1] NATURE, **136**, 225, Aug. 10, 1935.

I HAVE read with interest Sir Leonard Hill's letter and his paper on "A Method of Measuring the Air-way of the Nose" which appeared in the *Lancet* of

July 13. As the subject is of practical importance, I am sorry that experts do not seem to be in agreement as to its extent or as to its effect on the general health of the half of the community which is said to be affected by it. Considerable use by those commercially interested in domestic heating has been made of expert assertions on the subject, and these are widely quoted. It is difficult to find out the magnitude of the effect and whether it is of importance or not in other than pathological cases. Personally, I have never noticed it. Further information on this subject will be welcomed by everyone.

THE WRITER OF THE NOTE.

Perspiration and Erythema

PRELIMINARY spectroscopic experiments have been made to determine the absorption of ultra-violet light by human perspiration. The results, so far only qualitative, indicate that a film of sweat one millimetre thick absorbs light slightly in the region of 3300 A., very appreciably at 2900 A., and is practically opaque at 2700 A. Since sunburn is induced principally by light of wave-lengths lying between 2900 A. and 3100 A., these results indicate that human sweat acts as a partial protection against sunburn to a degree which depends upon the thickness of the layer.

Personal experience rather supports the point of view that sunlight effective in producing erythema is absorbed by perspiration; for, other things being approximately equal, one is usually sunburned more readily on a windy day than on a quiet one. Here the presumption is that the wind keeps the body cool and dry and thus nearly free of perspiration. Better evidence is that of a friend, H. C., who, while canoeing on the Mississippi River with G. P. on a very hot day, frequently dipped his arms into the river, and at the end of the day experienced a severe case of erythema on the arms. On the other hand, G. P., whose arms were likewise exposed to the sun, did not immerse them in the water and suffered merely a modest burn. Both canoeists had commenced the day with a normal summer tan. Assuming the two to have been comparable subjects, one is tempted to the opinion that the frequent immersion of the arms of H. C. kept them free of perspiration, while G. P. enjoyed the protection which the sweat afforded against the actinic rays of the sun.

The constituents of perspiration most likely to be effective in absorbing light in the neighbourhood of 2950 A. are urea, uric acid and certain amino acids. Urea absorbs light in this spectral region slightly, but is nevertheless present in relatively large amount in human sweat. Uric acid has an absorption band with a maximum at about 2900 A., but appears only in small amount in normal sweat. The amino acids, tryptophane and tyrosine, if they appear in sweat, may be effective in producing absorption since they each have an absorption band at about 2900 A.

The fact that normal urine, which contains relatively much more uric acid than does sweat, cuts off rather sharply all light below about 3100 A., suggests that perhaps uric acid may be the primary absorbing agent in human perspiration.

The Profession of Management

IN view of the forthcoming meeting of the British Association and the dominant place accorded to management in Section F* (Department of Industrial Co-operation), a brief explanatory statement of the position of management, as I see it, from a vocational and scientific point of view, may be of interest.

Management, which at the higher levels is the same thing as administration, is tending to become, or made, a 'recognised' profession, comprising (1) practitioners (that is, actual managers); (2) management consultants (corresponding to 'counsel' and 'specialist' in law and medicine); (3) management research workers (corresponding to those in science); (4) educators for (*a*) imparting instruction *about* management (and its associated subjects and sciences), (*b*) training (fitted) people *for* management, or, if already managers, for promotion or advancement.

It will be apparent from (1) that management is in reality not a subject but a functional activity, the activity of directing, organising, controlling and developing in an almost infinite variety of circumstances. Under (2) two functions are distinguishable: (i) management 'auditing' to improve or strengthen the management of an individual concern (in the case of a 'business' increased profits expected as a result), (ii) management 'auditing' to determine, in the case of a 'business', safety as regards financial investment, or suitability of any concern for investment of individual effort. Under (3) the work is largely method- and technique-invention, statistical inquiry and objective psychological investigation (managerial thinking, attitudes, training and vocational selection and guidance). The distinction under (4) is highly important. Its neglect is responsible for much of the ineffectiveness of some university courses. Education may be regarded as the 'mother' function of the new profession as a whole, but as in other fields, only supplementary or preparatory to learning by practical experience.

Since managerial action (or inaction) is based on human decisions and judgments, 'good' management should always be used in preference to the Continental 'scientific' management. 'Good' implies the maximum application of scientific method without eliminating the all-important factors of wisdom and morality.

Experimental Phonetics and Ancient Greek Verse

ANALYSIS of a macrophonic registration[1] of "Devon to Me!" spoken by John Galsworthy[2] showed that 15 of the 40 lines of the poem had a rhythmic form indicated by $\breve{} \smile \breve{} \smile \breve{}$; an example is the line "Where my fathers stood". This is the form known in ancient Greek metrics as the hypodochmius (for example, "Oed. rex", 1208). Twenty lines had the form $\breve{} \smile \smile \breve{}$; an example is "Watching the sea". This is the choriambus, a very common ancient form. Five lines had the form $\breve{} \smile \smile -\acute{} -$ as in "Taste of the cream pan!" This is the form termed adoneus. Every line of the poem was spoken with some form of ancient Greek rhythm. The registration of the first stanza of "Drake's Spirit" by Galsworthy himself showed that the line "I, Francis Drake" had the rhythm of the third epitrite $\breve{} \breve{} \smile \breve{}$ as in "Medea", 628, and that the line "When the land needs"

had the rhythm of the rising ionic ⏑ ⏑ – – as in "Phoen.", 1539.

A registration of "Hickory, dickory, dock" showed a rhythm of – ⏑ ⏑ – ⏑ ⏑ –; this is a hemiepes as in "Medea", 412. The line "Gems of a master's art" (Bridges, "Buch der Lieder") was spoken with the rhythm – ⏑ ⏑ – ⏑ –; this is one form of the dochmius as in "Agamem.", 1166. "Here a little child I stand" (Herrick, "Grace for a Child") registered with the rhythm – ⏑ – ⏑ – ⏑ –; this is a lekytheion as in "Phœn.", 642. "Tell me thou star whose wings of night" (Shelley, "The World's Wanderers") was spoken with the rhythm – ⏑ ⏑ – ⏑ – ⏑ –; this is the choriambic dimeter as in "Antig.", 332. "Fear no more the heat of the sun" (Shakespeare, "Cymbeline", 2, 4, 249) had the rhythm – ⏑ – ⏑ – ⏑ ⏑ –; this is the choriambic dimeter as in "Antig.", 107. "A wet sheet and a flowing sea" (Cunningham, "A Wet Sheet . . ."), yielded the rhythm ⏑ – – ⏑ ⏑ – ⏑ –; this is a form of the glykoneus as in "Iphig. Taur.", 1097. The line "Ein schönes, wohlgewachsnes Buch" (Ginzkey, "Das Buch"), spoken by the poet himself[3], showed the rhythm ⏑ – ⏑ – ⏑ – ⏑ –; this is the iambic dimeter, a common ancient form. "Die Damen im schönen Kranz" (Schiller, "Der Handschuh"), spoken by a German, registered with the form ⏑ – ⏑ ⏑ – ⏑ –; this is the ancient telesillion.

The lengths of the vowels in ancient Greek verse are known. The examples given here seem to justify the conclusion that, wherever the lengths of the vowels in ancient Greek verse correspond with the lengths in English and German verse as determined by registration and measurement, the rhythmic scheme is the same. Many—perhaps all—the ancient forms may be established on this principle. Greek metrics thus becomes an exact science consisting of numbers obtained by measurements.

Points from Foregoing Letters

PROFS. F. A. PANETH and G. P. Thomson state that during the bombardment of heavy hydrogen with positive rays (positively charged hydrogen atoms) they had obtained, like Harnwell, Smyth and Urry, measurable amounts of helium; they consider, however, that this is not helium of mass 3 resulting from atomic transmutation, but helium gas adsorbed on the walls of the glass discharge vessel, and afterwards released by the hydrogen.

The only way to explain satisfactorily the long life period of the radioactivity of potassium, according to Dr. K. Sitte, is to assume the existence of a rare isotope of mass 43, which loses an electron and becomes the calcium isotope of the same atomic mass.

From the transitory changes in the absorption spectrum of the liver enzyme catalase, when monoethyl-hydrogen peroxide is added to it, Dr. K. G. Stern deduces the formation of an intermediate compound. This compound breaks down less rapidly than the intermediate compound presumably formed between catalase and hydrogen peroxide, since in the latter case there is no apparent change in the enzyme spectrum.

Dr. E. E. Jelley has studied the dichroism of some rare-earth salts and has found that bands are missing from the absorption spectrum for certain ray directions and planes of vibration. These ray directions for zero absorption differ from band to band, and are not always coincident with the axes of the Fresnel wave surface. He considers that this is strong evidence that at least some of the electronic orbits of the incomplete *N* shell are fixed with regard to the crystal structure, and that the rare-earth ions as a whole are incapable of free rotation.

The magnetic susceptibilities of single crystals of thallium metal parallel and perpendicular to the hexagonal axis, and their variation with temperature as the crystal changes to cubic symmetry, have been investigated by Prof. S. R. Rao and K. C. Subramaniam. The authors consider that the hexagonal structure is due to the three valency electrons of thallium, while in the cubic structure only the single valency electron is active.

The elastic constants of glass have been calculated by Dr. E. Hiedemann from measurements of the velocity of short (ultra-sonic) compression waves. Observations were made with crossed nicols upon the nodal lines produced in a cube of glass by the transverse waves which bring about double refraction at the position of maximal elastic strain.

An additional wave produced by earthquakes, due to reflection first at the earth's surface and then at the boundary of the earth's core, has been identified at the Dominion Observatory, Wellington. This provides, as R. C. Hayes points out, a method of locating abnormally deep earthquakes from a single record near the epicentre.

Dr. V. B. Wigglesworth has shown that in the blood-sucking bug, *Rhodnius prolixus*, the corpus allatum secretes the active substance which prevents the appearance of adult characters ('metamorphosis') until this insect is full-grown; and also, in the mature female, a substance which causes development of the eggs.

The amount of nitrates and phosphates in the surface waters of the Pacific Ocean off the coast of New South Wales is reduced to a mere trace after the attainment of a maximum in diatom production (for example, in spring), according to Prof. W. J. Dakin and A. N. Colefax; this phenomenon is similar to that observed by Harvey and Atkins in the English Channel.

Experience suggests that one is not so likely to receive severe sunburn when the skin is covered with a thick layer of perspiration. Prof. W. H. Crew has made qualitative spectroscopic observations which show that perspiration absorbs, to a considerable extent, the erythema-producing rays of sunlight. The small amount of uric acid in human sweat may be the principal agent in causing this absorption.

Research Items

Early Bronze

PROF. CECIL DESCH points out the difficulties in determining the sources of ancient tin and copper in a discussion of the origin of bronze (*Trans. Newcomen Soc.*, 14, 1933-34). The term 'bronze' was applied loosely by archæologists to objects which on examination have proved to be copper. Many have supposed that the bronze age was preceded by a copper age, sometimes regarded as of a considerable duration; that the introduction of bronze was accidental; and that a composition of 90 to 10 was arrived at experimentally. This was probable only if native copper was first used and hardened by hammering, casting being discovered later. It is now known that true bronzes are found at a very early date together with copper. The presence of certain 'key' elements, such as nickel and arsenic, affords a clue to the origin of the copper ores. Of two specimens of native copper from Angora and Arghana, the latter was only 97·08 pure, the remainder being tin, iron, nickel and sulphur. On the other hand, the purity of certain ancient objects does not prove the use of native copper. Probably they were obtained by smelting a pure malachite ore. Early Mesopotamian objects are usually free from sulphur, which points to the use of oxidised copper ores. Nickel in early Mesopotamian objects has led to a search for ores containing nickel, and the tentative identification of the Magan of Sargon of Agade as a possible source in Oman. Recently, the presence of arsenic in certain objects has turned attention to Anatolia, Armenia and Caucasia generally. Zanghezour in Azerbaijan is mentioned as the source of Persian and Median copper, and the copper obtained here at the present day shows small quantities of nickel and arsenic. No metallic tin has been found before the eighteenth dynasty. There are few records of its occurrence in those areas of Asia with which the ancient Sumerians were concerned. Importation from Britain or Spain cannot be assumed. Bronze must have originated in the East, but the problem of its origin is unsolved.

Mud-Castle of the Han Dynasty, Chôsen

FOR some twenty years, Japanese archæologists have been engaged in exploring tombs of the Han Dynasty in Chôsen, one of the four provinces instituted by the Emperor Wu-ti in 108 B.C.; but in April 1935 investigation was extended to the 'dojô' (mud-castle), of which indications had been found. According to a report of the excavator, Yoshito Harada (*Proc. Imp. Acad.*, Tokyo, 11, 6), "discoveries of supreme value and importance" have already been made. The ruins of the dojô lie some 6 km. from Heijô in the midst of a tract studded with tombs of the Lo-lang period. The remains of mud walls, tiles and other objects in an area 0·8 km. square, now devoted to farms, pointed to the former existence there of buildings. Excavation brought to light a foot-way, 38 m. long by 8 m. broad. It was paved with tiles, but with marble at the margins. Remains of buildings, 10 m. by 8 m. in area, were excavated. On one wall was found a Korean heater of brick, with a chimney of stone and brick still standing. Among the objects found were a bronze tripod vessel, iron arrowheads, coins, crystal and glass beads, pottery, tiles, etc. The most valuable find, however, consisted of two clay sealings bearing impressions of the seals of Government officials of the districts of T'i-hsi and Pu-êrh respectively. Chinese historical records mention the former in both the earlier and later Han periods, but the latter was in existence only in the earlier. This sealing, therefore, serves to fix the date of the building as certainly not later than A.D. 25. This is the first example of Han architecture to be discovered. The purpose of the building is at present uncertain; but the great number of tiles bearing the inscription "Lo-lang-li-kuan" which have been found suggest that it was the Government office in charge of ceremony. Excavation is to be resumed in the autumn.

Researches on *Calanus finmarchicus*

A CONTINUATION of the important team work on plankton at the Millport Marine Laboratory by Drs. S. M. Marshall, A. G. Nicholls and A. P. Orr which has now been going on for some years has recently been published (*J. Mar. Biol. Lab.*, May 1934, Feb. 1935. "On the Biology of *Calanus finmarchicus*. Part 4. Seasonal Changes in the Weight and Chemical Composition in Loch Fyne. By A. P. Orr. Part 5. Seasonal Distribution and Size, Weight and Chemical Composition in Loch Striven in 1933, and their Relation to the Phytoplankton. Part 6. Oxygen Consumption in Relation to Environmental Conditions. By S. M. Marshall, A. G. Nicholls and A. P. Orr). Following the previous work on size and distribution (Pts. 1 and 2), an attempt was made to ascertain what changes of weight and chemical composition took place throughout the year. It was found that Stage V accounted for much the most important part of the total weight of the catch, and it is usually largest and heaviest when most abundant. Although smaller than the female *Calanus*, Stage V was from the beginning of June to the end of August considerably heavier; its weight fell during the spring and did not increase again until after the end of the first breeding period. In Loch Striven there were three main breeding periods, in February and March, May to June, and in July, with subsidiary broods in August and September. The first brood, which developed when the sea was at its coldest, consisted of *Calanus* of the largest size found during the year; after this there was a gradual fall, corresponding with the warming of the sea. Diatom increases corresponded with the three main spawning periods giving plenty of food for the nauplii. Experiments were made in order to determine the oxygen utilisation by male, female and Stage V. From the amount of oxygen used in respiration, calculations of the food required are made and these are compared with the results given by Pütter for *Calanus* and other copepods. The figures indicate that for Stage V (the most abundant form) and for the adults which require more, the amount of food required daily is very much lower than that calculated by Pütter for *Calanus*.

Crustacea from Polynesia

MR. CHARLES HOWARD EDMONDSON records some very interesting new species in his paper "New and Rare Polynesian Crustacea" (Bernice P. Bishop Museum Occasional Papers, 10, No. 24, 1935). *Mesocaris lauensis* is a new species for which a new genus is created in the Atyidæ. This was taken in a cave containing brackish water on the Island of Namaka and from a salty lake on the Island of Wangana in the southern Lau Islands, Fiji. It represents a very primitive type of Atyd with well-developed exopodites on all the legs and presenting other characters warranting a new genus, but is fairly closely related to *Xiphicaris Paratya* and *Palæmonias*, all of which have exopodites on all the legs, *Paratya* being the only one of these which has penetrated in any degree into the south-west Pacific area. The number of gills is identical in this genus and *Mesocaris*, epipodites being present on the third maxillipedes and all the legs but the last, and in the present species these are peculiarly shaped with a strong terminal hook and a constriction near the free end. Besides these there are seven pairs of gills. The eye pigment is considerably reduced both in the cave specimens and in those of the same species from the brackish-water lake, which is quite exposed. The lake is, however, connected with the sea by subterranean channels, and it is probable that underground caverns and passages connected with the lake have for a long period of time offered habitats encouraging adaptation to a cavernicolous existence. Among the many new finds, a Xanthid crab belonging to a new genus *Nullicrinus*, having atrophied antennæ, is described from Christmas Island.

Insects of Samoa

PART 9, Fasc. 2, pp. 33–104 of "Insects of Samoa", in course of publication by the British Museum (Natural History), consists of a summary by Prof. P. A. Buxton, dealing with the evidence that may be derived from a study of the insect fauna of these islands. While the collection of Samoan insects is far from complete, it forms a basis from which general conclusions may be drawn. Out of the 1,603 species of insects known to occur in Samoa, 49 per cent appear to be endemic. This percentage of endemism is notably lower than that which obtains, for example, in the Hawaian Islands and the Seychelles. The study of the insects, both of those which are absent and those which are present, leads to the same conclusion, namely, that the Samoan fauna is oceanic. There are, however, certain species of insects of specialised habits the occurrence of which is difficult to reconcile with this conclusion. It is clear, and generally admitted, that the fauna of Samoa is essentially Indo-Malayan, but one or two characteristic Australian groups have reached the islands, apparently by natural means. The problem as to how the existing forms of life, or their ancestors, crossed the ocean from Indo-Malaya is a difficult subject. Such questions have long puzzled zoo-geographers and, although we are not yet in a position to answer them, knowledge is advancing in certain particulars. The great stream of anti-trade wind, at no great altitude, may well carry insects and other forms of life eastwards. Recent work on insects found in the upper air suggests that air currents are a much more important factor in distributing small insects than has been realised. Also, the wanderings of oceanic peoples before the advent of the European may have had a considerable influence on the distribution of both plants and insects. In connexion with the transport of insects by means of the traditional floating logs, Prof. Buxton suggests that a study is needed of the effects of sea-water on all stages of insects which have a wide distribution among tropical islands.

The Rhododendron White Fly

THE common white fly of greenhouses is now a well-known plant parasite, but it has other near relations which appear to be equally destructive. Mr. G. Fox Wilson has described one of these (*J. Roy. Hort. Soc.*, 60, Part 6, pp. 264–271, June, 1935). The rhododendron white fly, *Dialeurodes chittendeni*, first appeared in 1926 and is now reported from numerous stations in the south of England. The account under review describes the various stages of the insect, and outlines its life-history. Damage to the host is illustrated by means of very clear photographs. Control may be effected by spraying the lower surfaces of infected rhododendron leaves with a white oil and nicotine emulsion. The Chalcid wasp, *Encarsia formosa*, which parasitises the greenhouse white fly, also attacks its relative on the rhododendron, but low night temperatures and the rather long life-cycle of the parasite militate against its successful use as a control measure.

Experiments on Plant Virus Diseases

THREE papers on various aspects of plant virus diseases by Dr. J. Caldwell, Rothamsted Experimental Station, have recently appeared. "The Control of Virus Diseases of the Tomato" (*J. Minis. Agric.*, 41, 743–749, Nov. 1934) recommends the removal of weeds, avoidance of smoking tobacco (which transmits tobacco mosaic), the early removal of infected plants, and routine fumigation to keep down insect vectors. "Experiments on the Purification of the Virus of Yellow Mosaic of Tomato" (*Ann. App. Biol.*, 22, 68–85, Feb. 1935) discusses various methods of purification, and shows that there is no evidence that virus can be recovered in a crystalline form; infectious material always contained organic nitrogen. The virus was found to be active between *p*H 2·0 and 10·5. A paper "On the Interactions of two Strains of a Plant Virus; Experiments on Induced Immunity in Plants" (*Proc. Roy. Soc.*, B, 117, 120–139, March 1935) shows that two strains of yellow mosaic virus can be isolated. These are apparently quite distinct as regards characters *in vitro*, and it is suggested that many anomalies in symptom expression of this and other virus diseases can be explained by assuming the presence of strains in the causal agent. A virus strain may inhibit the development of another strain in the same host; the two strains may multiply separately and independently; the second virus may multiply without causing symptoms, or it may add to the severity of the disease produced by the first strain.

Cowpea Rust

A RATHER serious fungus disease of the cowpea (*Vigna sinensis*) reduces the yield of this crop in Egypt. It has been known since 1919, but a full study of its life-history has recently appeared by Dr. Tewfik Fahmy (*Min. Agric. Egypt, Bull.* No. 144, Publications Office, Govt. Press, Bulâq, Cairo, 1935. P.T. 5). The cause of the disease is a rust fungus, *Uromyces vignae*, and produces uredospores,

teleutospores, spermatia and æcidia upon the cowpea. The ten pages of the bulletin are devoted to descriptions of the fungus and its symptoms, with proof of its pathogenicity. Spermatia and æcidia appear during July and August, being quickly followed by uredo and teleuto stages, as the temperature gets cooler and the humidity increases. Twelve half-tone illustrations portray the symptoms and the causal fungus, and a further bulletin, on the selection of varieties of cowpea immune to the disease, is promised.

Kinetics of Photosynthesis

In a recent theoretical paper, Prof. E. C. C. Baly (*Proc. Roy. Soc.*, B, **117**; 1935) has derived equations to express the known variations in the rate of photosynthesis in varying conditions. The treatment is based on the supposition that the photosynthetic process consists of three distinct stages: (*a*) the union of chlorophyll *a* with hydrated carbon dioxide; (*b*) an oxidation-reduction reaction in which the chlorophyll *a* – carbonic acid complex is converted photochemically to chlorophyll *b* and activated formaldehyde; (*c*) the Blackman reaction in which, it is suggested, chlorophyll *b* is reduced by carotin to chlorophyll *a*, and xanthophyll is produced. The condition in which the velocity of oxidation of chlorophyll *a* to chlorophyll *b* in the light reaction is equal to the velocity of its regeneration by the Blackman reaction is described as a "photostationary state". It is this condition which is defined by the equations, which are shown to express with noteworthy accuracy the variation in rate of photosynthesis with temperature, the theoretical curves agreeing well with Emerson's data on *Chlorella*. These equations are extended to express the influence of varying total light intensity, carbon dioxide concentration, intermittent illumination and the effect of poisons. Prof. Baly's view that the primary photosynthetic reaction consists of two consecutive light reactions, stimulated by blue and red light, is expressed by equations modified in this respect, and data calculated from these equations agree well with the observations of Briggs and Warburg on the effects of varying the relative intensities of red and blue light. Baly's formulation of the Blackman and light reactions will not be received without criticism, but if it is admissible as a basis for hypothesis, the subsequent mathematical treatment will form an interesting addition to the theory of photosynthesis.

Eocene Foraminifera

In a memoir on the Upper Eocene Foraminifera of the south-eastern United States (U.S. Geol. Surv., Prof. Paper 181; 1935), J. A. Cushman describes 203 species or varieties from the Jackson formation. The sediments are variable in character, some being of very shallow water nature, others much deeper. The foraminiferal faunas show differences corresponding with differences in the depth of the deposits. The shallow water type resembles the fauna of the shallow water in the Indo-Pacific region rather than the living fauna of the West Indies. On the other hand, the deeper water fauna is much more closely allied to the fauna still living in the Gulf of Mexico and the West Indian region. T. W. Vaughan and others have already pointed out the resemblances of the early Tertiary corals, etc., of the West Indies to genera now living in the Indo-Pacific region.

Sound Insulation

The issue of the *Journal of Research of the Bureau of Standards* of June contains Research Paper 800 on "Recent Sound Transmission Measurements at the Bureau of Standards" by Messrs. V. L. Chrisler and W. F. Snyder. The source of sound is a loudspeaker mounted on a rotating arm so that it describes a circle 5 feet in diameter. It can emit nine frequency bands between 128 and 4096 cycles per second, each band of width 20 per cent of its middle frequency. The chamber in which the sound is produced has walls 6 inches thick of reinforced concrete and is about 10 ft. × 12 ft. × 12 ft. It is insulated by 3 inches of air from a chamber by its side and another above it, and the panels to be tested can be inserted in the wall or ceiling. Measurements of sound pressure are made by means of a microphone placed in turn on each side of the panel under test and at different distances from its centre along its normal. Detailed results are given for 28 panels tested, and confirm the laws that a solid homogeneous wall must be very heavy to be a sound insulator, and that dividing it into layers as loosely connected as possible increases greatly its sound insulating properties.

Transport Numbers of Salts

The older measurements of transport numbers by the so-called moving boundary method were subject to considerable doubt, and the utility of the method had been questioned. A series of careful measurements with the use of improved apparatus made by MacInnes and others showed that the method is capable of giving very satisfactory results, and it has been used to determine the transport numbers of several salts. On the simple ionic theory, the transport number is regarded as constant; but it is now known to depend on concentration, so that a comparison of conductivities at different concentrations does not give the degree of ionisation without further correction. The mobilities of individual ions as functions of concentration may be obtained by combining transport numbers with conductivities, and accurate values of activity coefficients may be obtained from transport data and electromotive force measurements with certain cells with liquid junctions. Some further measurements of transport numbers by the moving boundary method, and a useful summary of previous results, are given by L. G. Longsworth (*J. Amer. Chem. Soc.*, **57**, 1185; 1935). The paper contains tables for the transport numbers of several salts in aqueous solutions at 25° at various concentrations. Two types of boundaries are distinguished, namely, autogenic boundaries, formed automatically by the electrochemical solution of an appropriate metal anode, and sheared boundaries, made by the superposition of leading and indicator solutions. The latter involves a special mechanism, first described by MacInnes and Brighton, by means of which one solution is superposed on another with a minimum of disturbance to either solution. Although the moving boundary method may be used over a wide range of concentration if the proper indicators are available, it is most useful in the interval 0·01–0·2 *N*. Outside this range, sources of error become important. Solvent and volume corrections must be applied, the first for the conductance of the solvent and the second for the changes in volume of solution by transfer of electrolyte. Recent measurements by the Hittorf and moving boundary methods are in agreement.

An Apparatus for Rearing Marine Organisms in the Laboratory

By Dr. F. G. Walton Smith (Commonwealth Research Fellow)

ALTHOUGH the life-histories of the most important marine organisms have been worked out in the past, there is very little known in many cases regarding the detailed changes that take place during the critical stages separating larval life from that of the adult, while the study of the physiology of invertebrate larvæ has been almost entirely neglected.

These gaps in our knowledge are partly due to the minute size of many of the larvæ, but also in large measure to the difficulty experienced in rearing them in the laboratory. Even though the most scrupulous care be taken in sterilising instruments and vessels, and in keeping physical and chemical conditions of the environment 'normal', this difficulty remains; and it is a common experience to find that larvæ will live in plunger jars for days and weeks longer than the natural period of their free-swimming existence without increasing in size or developing organs characteristic of the metamorphosing stages. On the other hand, attempts to provide food in the form of organisms isolated from the microplankton, though occasionally successful, are usually doomed to failure, owing to the ease with which the physical, chemical and biological factors of the environment in a restricted volume of water pass beyond our control, and to our ignorance of the actual food requirements.

If, however, a continuous flow of fresh sea-water can be supplied to the organisms in sufficient quantity, not only will physical and chemical conditions remain stable, but also food organisms of the kind available under natural conditions will be provided, and in sufficient concentration to permit of normal growth and development. It was found necessary recently, in order to study the metamorphosis and biology of the larval oyster, to construct an apparatus that would satisfy this requirement, and make it possible to undertake the rearing of all stages in development with a high degree of certainty. The apparatus (Fig. 1) and procedure described below have given consistently satisfactory results, not only with the larvæ of the common American oyster, but also with later stages of *Ostrea equestris*, and species of *Chiton*, *Crepidula* and *Fissurella*.

The type of vessel employed is the cylindrical jar used in some fish hatcheries, and is about 18 in. high and 6 in. in diameter, with a conical base (*B*). This shape has the advantage that on stopping the flow of water the larvæ quickly settle to the bottom and are readily collected. In order that the flow of water may not carry away the small larvæ (early stages of *Ostrea virginica* are less than 0·06 mm. in smallest dimension), the outflowing water is removed from the rearing jar by means of a siphon (S_3), the wide mouth of which (F_2) is covered by a fine net of bolting silk. Rapid clogging of the pores of this material is prevented by dipping the mouth of the siphon under the surface of molten paraffin wax melting at a temperature of 48° C. and then blowing air through the other end as it is removed. The resulting smooth coating of wax on the fibres of the net seems to prevent the entanglement of the larvæ, and allows the filter to work efficiently for a much longer period than otherwise would be the case. The net is fitted to the siphon by means of a rubber band.

The sea-water supply is taken from the reservoir feeding the main laboratory circulation, replenished by pumping from the sea once or twice a week. Where there is no such source of supply, it is necessary to use a supply tank which is replenished when needful with sea-water taken at high tide.

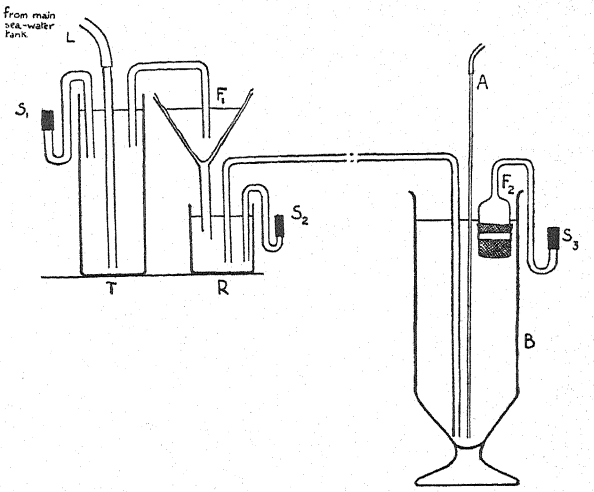

FIG. 1.

Whereas the exit siphon is placed at the top of the jar, the sea-water enters the vessel through a glass tube extending to the bottom of it, thus making a good circulation of water possible. It is important that the sea-water supply should also be filtered, and to the same extent as the outflow, in order to guard against the accumulation of detritus and the admission of predatory organisms. This is conveniently carried out by means of a square piece of bolting silk supported in a filter funnel (F_1). Aeration and circulation of the sea-water in the jar are accomplished by means of a glass tube (A) connected with a compressed air supply and extending to the base of the jar.

In order to prevent the sea-water from entering the jar faster than it is removed, with subsequent loss of the larvæ, and in order to prevent an overflow from the filter funnel, a constant level siphon (S_2) is attached to the reservoir (R) supplying the rearing jar, and a similar arrangement is fitted to a vessel (T) feeding the filter. The constant-level siphons may be adjusted by means of small pieces of rubber tubing on the outer arms. The rate of flow of the sea-water through the rearing jar is regulated in this way, and is dependent upon the vertical distance between the outflow of siphons S_2 and S_3.

The use of this apparatus is not confined to the rearing of organisms alone. A series of rearing jars may be connected to the same supply reservoir, and if eggs from a single artificial fertilisation are distributed among them in equal numbers, they will

be able to develop under exactly similar conditions, providing a basis from which biological and physico-chemical conditions may be varied for experimental purposes. In order to analyse food requirements, for example, jars to which food organisms and solutions of different kinds are added, and which are supplied with sea-water filtered through a porcelain candle filter, may be set up for comparison with the arrangement previously described.

This apparatus has been found to give a sufficient approximation to 'normal' conditions to enable larvæ to be reared through the most critical stages of development, while in use at the Beaufort, N.C., station of the U.S. Bureau of Fisheries, this summer. My acknowledgments are due to the Bureau and to Dr. Herbert F. Prytherch, director of the Station, for hospitality and advice accorded to me during the time when I was making use of it there.

Archæological Research in Western China

ALTHOUGH archæological research in China has not yet afforded confirmation of the annals of the third millennium B.C., with which its recorded traditions open, excavation in the north and centre has brought to light not only cultures of the neolithic and bronze ages, but also inscriptions in a primitive script, which in a measure corroborate tradition and justify the attribution of authenticity to the dynasty of a period of some centuries before that of Cheo (1122 B.C.), hitherto regarded as the earliest dynastic record worthy of any degree of credence. The west must now be added to the regions of China in which archæological research has produced not only evidence of early civilisation, but also corroboration of a record which stands in a different category.

Recent excavations at Hanchow (*J. West China Border Research Society*, **6**, 1933–34) point to an early cultural connexion of the west of China with the north and centre, which may even go back to a much earlier date, if, as is suggested by an eminent Chinese scholar, Dr. Ko Mo Jo, an inscription on bone tablets from Anyang, which records the appearance of men of Shuh in the fighting ranks, and belongs to the Yin dynasty (1400–1122 B.C.), may be taken to refer to Szechwan, of which the ancient name is Shuh. For the fortunate result by which this important addition has been made to knowledge of the prehistoric cultures of China, archæology is indebted to members of the West China Border Research Society, and more especially to Dr. David Graham, curator of the West China Union University Museums, who intervened at a crucial moment to guide the zeal of the Chinese authorities for excavation into channels which would ensure the scientific value of the investigation.

The excavation at Hanchow is one only of a number of activities in which the West China Border Research Society, which was founded in 1922, acting in close co-operation with the Union University, is promoting the advancement of scientific research in the extremely interesting and important border area of western China and eastern Tibet. Its headquarters at Chengtu serve as a focusing point for activities in geographical exploration and studies in anthropology, botany, zoology and medical science, which carry on the scientific work of members of the missionary bodies, who promoted the West China Union University. By their own researches and by their co-operation with members of other scientific expeditions, they did much to promote scientific knowledge of this region long before the University came into being in 1910. The University Museums, which now have 53,334 specimens, distributed among the three Museums of Archæology, Art and Ethnology, the Natural History Museum and the Museum of Medical and Dental Sciences, owe much to their efforts, especially in the ethnographical section, which contains material such as cannot be found in any other museum. The Society's journal, now in its sixth volume, contains much valuable matter, especially worthy of regard in the anthropological world, as the Society, both in its publications and in the organisation of research among its members, is bound in the terms of its constitution to concentrate on regional and other investigations which bear on problems relating to the little-known non-Chinese peoples of the area.

As regards the excavations at Hanchow referred to above, the accidental discovery in 1931 of stone and jade rings, knives, discs and other objects in a pit at T'ai-p'ing-ch'ang, eighteen *li* from Hanchow, when an irrigation ditch was being deepened, pointed to the possibility of a prehistoric burial, which was confirmed by systematic excavation in 1934. In addition to the original pit, the ground immediately surrounding was carefully explored and several points in the area were also tested. No further grave pits were found, but everywhere there was abundant material which appeared to be mainly the refuse from a group of ancient pottery kilns.

The preliminary account of the excavation includes also an analysis of the physical characters of the jade and stone objects by Prof. D. S. Pye and of the pottery by Prof. H. B. Collier. A comparison of the culture with that found at Yang Shao and Anyang in Honan and that from Sha Kuo T'un in Fengtien points to interesting resemblances as well as differences. Thus there is no painted pottery at Hanchow or Sha Kuo T'un such as was found by Dr. J. G. Andersson at Yang Shao. Both the Hanchow and the Yang Shao cultures have large and small stone axes, chisels, knives, pestles or hammers, and flat discs, and both incised and cord-marked pottery. In both the potter's wheel is known. At neither, nor at Sha Kuo T'un, is there metal; whereas at Anyang there is abundant bronze, associated with a primitive writing on bone, bone implements and painted pottery.

Though Yang Shao and Sha Kuo T'un are classed as neolithic, the use of the wire saw at Hanchow and resemblances to Cheo objects suggest that the Hanchow site is later than æneolithic. In all probability it cannot be later than the beginning of the Cheo dynasty (1122 B.C.); but it is almost certainly later than the bronze culture of Anyang, which belongs to the Yin dynasty (1400–1122 B.C.). Thus it must represent a retarded development of the west.

Veneer and Plywood

FOR veneers and plywood, some of the hard tropical timbers, often showing beautiful colouring and figuring, are becoming better known. Research on wood for veneer and plywood has been carried out for some time at the Research Institute at Dehra Dun. In *Indian Forest Records* (Economy Series, **20**, 14. Delhi: Manager of Publications, Dec. 1934), Mr. W. Nagle, who is in charge of the Woodworking Section, discusses the "Testing of Indian Timbers for Veneer and Plywood". The purpose of the monograph is "to assist, as far as possible, the advancement of the plywood industry in India, and to further the use of indigenous timbers for veneer and plywood work".

Only those who have followed the development in the use of plywood during the last two decades will have a conception of the variety of purposes to which it is put at the present day. The author reminds the reader that the art of veneering was practised by, and certain forms of laminated construction were used by, the ancient Egyptians. But in Great Britain and for many centuries in Europe, solid wood was used both in house construction and for furniture. Modern demands for luxury articles at a cheap price have assisted and encouraged the use of plywood; but it would be misleading to think that the great demand for this material has been the result of any consideration for the conservation of valuable timbers. The truth is that at the present day every country which possesses areas of forest containing valuable, that is, luxury timbers is, by means of research work and otherwise, endeavouring to place them on the world markets.

It is well known that plywood has come into use in the manufacture of furniture and panelling. But it is worthy of placing on record the following list of other articles which are nowadays formed or built out of this fabricated material: cabin trunks, suit cases, perambulators, and even musical instruments such as violins and mandolins are made of either veneer or plywood. The modern motor-car has considerable amounts of plywood in its make-up, for example, floor boards, hood-stays, body-work, roofing and panelling. Other plywood or veneered articles in common use are chairs, theatre seats, wall panelling and ceilings, screen scenery and stage buildings for the cinema industry and theatres, railway carriages, dining saloons and 'sleepers'. The modern ship is fitted with plywood tables, bulkheads and general appointments. Parts of motor-boats, canoes and life-boats are often constructed of the same material; also aeroplanes and airships. Finally, chests are now made for tea, opium, cement, rubber, etc.; as also fruit and cigarette boxes.

It will be obvious that the above list is capable of indefinite extension. That it has reached its present dimensions gives evidence of the considerable amount of research and experimental work which has been carried out during the past few decades.

Mr. Nagle's monograph is based on research carried out during the past ten years with Indian timbers, upon which little was known as to their suitability or otherwise for veneers and plywood. It is technical in character, with a number of interesting photographs, and deals with some forty-two Indian timber trees.

Genetics of Size and Form Factors

THE problems of size and form inheritance are more difficult than many other problems in genetics, partly because the character units cannot usually be directly observed; they are often represented by multiple factors in the germ plasm, and they are also obscured by fluctuations.

Messrs. Sinnott and Dunn (*Biol. Reviews*, **10**, No. 2) have summarised our knowledge of the effects of genes on the development of size and form in plants and animals. Their summary is particularly useful because they emphasise the developmental and physiological aspects of size inheritance, although making it clear that fixed genic differences are involved. They point out that some dwarf types both in plants and animals are due to single factors, while many other size differences are due to several multiple factors. The differences may be in cell size, as in some of the polyploid and trisomic forms, or in cell number, or to both acting together. Size genes may depend upon general developmental differences controlled by particular metabolic rates.

In races of large rabbits the rate of cell division very early shows itself to be more rapid, and there is evidence that such races have a higher concentration of sulphydryl. Differences in fruit size in tomato varieties are due to differences both in cell number and cell size. Up till the time the flower opens, all the tissues of the ovary are meristematic. Subsequent growth is due to increase in size of the cells. In large-fruited varieties the ovary is larger, but cell enlargement is also carried much further. There appears to be a particular schedule or pattern of growth, involving both cell size and cell number, in each variety. The study of the inheritance of size of parts or organs involves heterogonic growth and Goldschmidt's physiological theory of heredity.

The conception of genic balance is involved, as in the trisomic Daturas, where the genes in one chromosome increase and those in another decrease the size of the pith, while other chromosomes affect the relative amounts of xylem and phloem. Thus while size genes may be general in their action, they may also have a special influence on certain parts. As shown by studies of inheritance of fruit shape in *Cucurbita* and the combs of fowls, as well as the proportions between various bones, it is evident that shape factors usually affect not single dimensions but two or three dimensions, through differences in growth rate.

Science News a Century Ago

Submarine Navigation Experiments

The Times on September 1, 1835, said: "According to the Paris papers, some curious experiments have lately been made at St. Ouen near Paris, with a submarine vessel, the invention of M. Villeroi, the engineer. The vessel is of iron, and of the same shape as a fish of the cretaceous tribe. Its movements and evolutions are performed by three or four men, who are inside, and who have no communication with the surface of the water, or the external air. With this machine navigation can be effected in spite of currents; any operations may be carried on under water, and it may be brought to the surface at will, like an ordinary vessel. It was with a machine similar to this that the project was formed in 1821 for getting away Napoleon from St. Helena. The Société Générale des Naufrages (protector, the King) has appointed Admiral Sir Sidney Smith, Count Godde de Liancourt, the Baron de St. Denis and Dr. Daniel St. Antoine to report on the experiments to be made at St. Ouen."

Ireland and the British Association

THOUGH the British Association meeting in Dublin in August 1835 was generally regarded as a success, some adverse comments on it were made in the *Dublin University Magazine*, extracts from which were published in *The Times* on September 4. "We cannot conceal our conviction," the *Magazine* said, "that for the purposes of the advancement of science the association is little better than useless. . . . The association, we prophesy, will soon see its end. . . . We rejoice, however, that it has lived long enough to visit Ireland; we rejoice that its visit to this island has been marked by so many traits that confer honour upon our country and our countrymen. We rejoice in anything that can confer honour upon 'ould Ireland', and so having said enough, perhaps some will think too much, upon a subject which we could not pass over in silence, we will leave the 'savans' and the association to go their ways in peace, and we will return with a good heart and an honest purpose to our own labours—labours that, though we may say it 'that should not say it' will do more than 50,000 British Associations to make that same 'ould Ireland'

'What she ought to be—great, glorious and free,
First flower of the earth, and first gem of the sea'."

Lyell in Switzerland

ON September 6, 1835, Lyell wrote to Viscount Cole (afterwards Earl of Enniskillen) from Meiringen, giving an account of the work he had done in Switzerland just before he left to attend the meeting of the German naturalists at Bonn. He had visited Berne, made excursions to Neuchâtel and the Jura and had taken soundings in the Lake of Thun. "But I found," he wrote, "when I attempted to understand the geology of the neighbourhood of the lake of Thun, even with Studer's newly published book and map and sections as he calls them in my hand, that I could not at all comprehend it, nor make out what he meant by his numerous formations. I therefore determined to make myself master if possible of the geology of this part of Switzerland, on which much more has now been written than on any other part of the Alps, before I make an attack on less known districts. This I have in some measure accomplished; but in doing it and climbing the Jungfrau and the Urbach Sattel, I have spent the time which was to have been given to Glaris which I hope, however, is postponed. I must now proceed at once on my way to the Bonn meeting. . . ."

One of Faraday's Mistakes

FARADAY'S entry in his "Diary", on September 6, 1835, opens with the paragraph: "Rose tells me that Berzelius in his annual account objects to my antimony proto sulphuret, and I am therefore hastened to its examination the first thing this autumn, having meant to defer it awhile before Rose told me this."

The supposed new compound had been referred to by Faraday in his "Seventh Series of Experimental Researches in Electricity", published in 1834, and described as having been prepared by fusing together the "ordinary sulphuret of antimony" with metallic antimony. He now, in September 1835, repeated the fusion more carefully, and analysed the product. The result differed from that previously obtained, for on September 12 the entry appears: "My former conclusions appear to be wrong, whatever the cause of this difference may be". He thereupon wrote off to the *Philosophical Magazine* withdrawing the new compound, saying that Prof. Rose on a visit to London had told him of Berzelius's objections, and that he had been "induced to make more accurate experiments on that point, which showed me my error". The letter, with a translation of Berzelius's paper, was duly published in June 1836.

Societies and Academies

PARIS

Academy of Sciences, July 8 (*C.R.*, **201**, 105–180). RICHARD FOSSE, PAUL EMILE THOMAS and PAUL DE GRAEVE: The estimation by weight and the identification by elementary analysis of small quantities of formol in very dilute solutions. The method is based on the reaction of formol with β-naphthol, and determines formol at concentrations between 30 and 200 parts per million, with an accuracy of one per cent or less. HENRI DEVAUX: The insolubility of thin plates of albumen. H. GRUYELLE and CHARLES POISSON: The magnetic anomaly of Tsiafajavona. MARC KRASNER: The theory of the ramification of ideals. H. AUERBACH and S. ULAM: The number of generators of a semi-simple group. PAUL MONTEL: Positive harmonic functions. OCTAVE ONICESCU: Holotope functions. ANDRÉ AURIC: An empirical formula giving the distances at which the successive rings of the nebular hypothesis are formed. MLLE. MARGUERITE ROUMENS: The systematic inclination to the west of the equatorial solar prominences of mean latitudes. DANIEL BARBIER, DANIEL CHALONGE and ETIENNE VASSY: The continuous spectrum of Nova Herculis. DIKRAN G. DERVICHIAN: The interpretation of the Eötvös constant and of its different values. NICOLAS STOYKO and RAYMOND JOUAUST: The propagation of short radio-electric waves in the region of the polar aurora. LOUIS NÉEL: The number electrons which contribute to the paramagnetism of nickel. The study of nickel alloys shows that an electron of the alloy metal annuls the magnetic contribution of a nickel electron. There is complete continuity between ferro- and para-magnetism, and

the same electrons intervene in both cases. LÉON and EUGÈNE BLOCH: The spectra of zinc, cadmium and mercury in the extreme ultra-violet. GEORGES DÉCHÊNE: The influence of the passage of an electric current on the phosphorescence of zinc sulphide. MAURICE CURIE: The hyperbolic law of the decline of phosphorescence. MAURICE PROST: The radiation accompanying the dehydration of quinine sulphate. The ease with which the radiation can be deflected shows that it is not due to large ions, thus differentiating this emission from that arising from the oxidation of phosphorus. HENRI MOUREU and PAUL ROCQUET. The structure of phosphorus pentachloride and of phosphorus pentamide $P(NH_2)_5$. PIERRE CARRÉ and DAVID LIBERMANN: The reaction of thionyl chloride with *m*- and *p*-aminobenzoic acids. ROBERT LANTZ: Study of the mechanism of the monosulphonation of naphthalene. GEORGES DARZENS and ANDRÉ LÉVY: The action of organomagnesium compounds on methylnaphthalenic and phenanthrenic esters. JACQUES DE LAPPARENT: The stages of the metamorphism of the Samos emeries. PIERRE DRACH: The modifications undergone by the skeleton in the decapod Crustacea before casting the shell. GEORGES A. NADSON and MME. CATHERINE STERN: The action of metals at a distance on germinating seeds. The inhibiting effect on growth produced by plates of various metals is shown to depend on the radioactivity of the surrounding air. MME. VÉRA DANTCHAKOFF: The differences of sensibility of tissue receivers towards folliculin at various embryonic stages. MME. MARIE PHISALIX and FÉLIX PASTEUR: The action of short waves on antivenom snake sera as well as on their neutral mixtures with the corresponding poisons. THÉOPHILE CAHN and JACQUES HOUGET: The transport of lipids in the animal organism. ANDRÉ BOIVIN and MME. LYDIA MESROBEANU: The presence of a 'complete' antigen and of a 'residual' antigen in various bacteria. A. BESREDKA, I. MAGAT and P. BESNARD: The importance of the mode of entrance in the evolution of the Pearce-Brown epithelioma. Testicular epithelioma of the rabbit, resulting in fatal generalised cancer, changes its character when it is inoculated under the skin. The tumour on the skin, although epitheliomatous in structure, is benign and is resorbed. PIERRE LÉPINE: The comparative action of immersion in glycerol and of freezing on the preservation of the virulence of rabic marrows. The usual method of preservation in glycerol at about 0° C. leads to a gradual loss in activity, due to the action of the glycerol. Freezing at − 10° C. leads to no loss of activity for at least 70 days. CONSTANTIN LEVADITI, RENÉ MARTIN, ANTOINE BONNEFOI and MLLE. RACHEL SCHŒN: The etiology of mumps. RAYMOND-HAMET: Some pharmacological effects of ergometrine, a new alkaloid from ergot of rye. JEAN CUILLÉ, CHELLE and BERLUREAU: The identity of French and Algerian ovine anaplasmosis.

LENINGRAD

Academy of Sciences (*C.R.*, 2, Nos. 3–4, 1935). A. GELFOND: Approximations of transcendent numbers by algebraic numbers. J. PRIVALOV: Some questions of the theory of subharmonic functions (2). E. KUZNECOV: The law of probability of an accidental vector. A. POPOV: Some results obtained by V. Brun. I. S. ASTAPOVICH and V. K. FEDYNSKIJ: Heights of meteors. G. KRUTKOV: A note on the 'great complexes' of Gibbs and the method of Darwin and Fowler. W. ARKADJEV: Magnetic and electric spectra in high frequency. V. FREDERICKS, G. MICHAJLOV and D. BENESZEWICZ: Electroconductivity of an anisotropic fluid. V. FESENKOV: Luminosity of the night sky at Kitab, Tashkent and Kuchino. N. N. KALITIN: Intensity of the radiation from the sky at wave-lengths 3292 A., 3595 A. and 3944 A. E. A. SHILOV and G. V. KUPINSKAJÁ: Rate of hydrolysis of chlorine. N. D. ZELINSKIJ: Catalytic aromatisation of benzines. A. L. KLEBANSKIJ, U. A. DRANICINA and I. M. DOBROMILSKAJA: A new trimeric combination of acetylene, acetylenyldivinyl. N. I. KOBOZEV, S. S. VASILJEV and E. E. HALBRAICH: Catalytic influence of mercury vapour on the cracking of methane in a glow discharge. V. V. TCHELINZEV: Oxonic compounds. Acid compounds of chinones and their chlorination and bromination. G. V. TCHELINZEV and E. D. OSETROVA: The α-benzoylbutyrolactone, γ-benzoyl-propyl-alcohol and γ-benzoyl-propyl-bromide. M. K. DJAKOVA and A. V. LOZOVOJ: Hydrogenation of Cheliabinsk brown coal. V. TETERIN and A. IVANOV: Investigations on the synthesis of vitamin A. (1) Action of magnium on a mixture of 1,4-dibrombutene-2 and ionon. A. E. FERSMANN: Energy indices in geochemistry. S. D. CHETVERIKOV and A. F. FIOLETOVA: Celadonite from Koktebel, Crimea. V. I. DANILOVICH: Scheme of stratigraphy of the Khingan complex. O. S. VIALOV: A classification scheme of tertiary strata in Ferghana. O. S. VIALOV, S. F. MASHKOVCEV and G. I. SHATOV: Cretaceous basalt in Ferghana. O. L. EINOR: A detailed stratigraphical section of the super-carboniferous of the Kizel district, Urals. P. P. LAZAREV: The action of a condenser discharge from the point of view of the ionic theory of excitation. D. KOSTOFF and I. A. AXAMITNAJA: Studies on polyploid plants (9). Chemical analysis of diploid and their autotetraploid plants. L. P. BRESLAVEZ: Differential fertilisation of the hemp plant. B. M. GOLUSH: Changes of the plasma permeability induced by temperature effects. R. M. BARCINSKIJ: The agent stimulating sprouting of *Orobanche cumana* seeds. S. V. SOLDATENKOV: Data on the chemistry of the artificial ripening of the Japanese persimmon (*Diospyros kaki*, L.). I. KOZHANCHIKOV: Role of anoxybiotic processes in the larval diapause of some *Pyralidæ*. L. K. LOZINA-LOZINSKIJ: The anabiosis of larvæ of *Pyrausta nubilalis*, Hübn., after freezing. J. D. KIRSCHENBLATT: The problem of the origin of some nidicoles (nest dwellers). B. A. ZENKOVICH: Whale fœtuses.

MELBOURNE

Royal Society of Victoria, July 12. F. CHAPMAN and IRENE CRESPIN: Foraminiferal limestone of Eocene age from North-West Division, Western Australia. Eocene sedimentary rocks have been discovered for the first time in Australia, during the survey by Messrs. E. A. Rudd and D. Dale Condit, of the Bullara Area. Two samples of limestones from slightly different localities contain a foraminiferal fauna of a Lower to Middle Eocene age. R. A. KEBLE: Victorian Tertiary flora and its influence on sedimentation. The plant beds at Narracan, Dargo, Darlimurla, Bogong, Berwick and probably Moonee Ponds are regarded as of Eocene age, those at Bacchus Marsh, Mornington, Haddon and the lignites at Yallourn (Morwell), Altona and other places as Oligocene, the Pitfield plant bed as Lower Miocene, and the Sentinel Rock plant bed as late Miocene. The flora indicates

that a subtropical climate persisted to the middle of the Miocene and the vegetation was similar to that in the region of the Tropic of Capricorn. The Sentinel Rock flora suggests a temperate climate and vegetation similar to that in Victoria and Tasmania.

VIENNA

Academy of Sciences, June 13. ERNST ROUSCHAL: The dependence of the intake of water by entire plants on the temperature. The lowered absorption of water brought about by cooling the roots of plants to 0° C. does not resume its normal value when the temperature is afterwards made normal, and the course of the recovery varies with different plants. GERHARD KIRSCH and FRITZ RIEDER: Disintegration of nitrogen by neutrons. In this disintegration, two processes, both connected with capture of the neutron, take place. In one, an α-particle and B^{11} are formed by emission, and in the other, which is much rarer and is effected mainly by the more rapid neutrons, C^{14} arises, presumably by proton emission. HERBERT SCHOBER: Measurement of the daily and monthly variation in the length of the ultra-violet for the solar and zenith spectra at Watten (Tyrol). OTTO DISCHENDORFER: Condensation of benzoin and hydroquinone.

Forthcoming Events

[Meetings marked with an asterisk are open to the public.]

Sunday, September 1

BRITISH MUSEUM (NATURAL HISTORY), at 3 and 4.30.—M. A. Phillips: "Birds".*

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (NORWICH MEETING)

Wednesday, September 4

At 8.30 p.m.—Prof. W. W. Watts: "Form, Drift and Rhythm of the Continents" (Presidential Address in the Agricultural Hall).

Thursday, September 5

At 10 a.m.—Prof. W. N. Haworth: "The Molecular Structure of Carbohydrates" (Presidential Address to Section B).

Prof. F. Balfour-Browne: "The Species Problem" (Presidential Address to Section D).

Prof. F. Debenham: "Some Aspects of the Polar Regions" (Presidential Address to Section E).

Mr. J. S. Wilson: "Stability of Structures" (Presidential Address to Section G).

Friday, September 6

At 10 a.m.—Dr. F. W. Aston: "The Story of Isotopes" (Presidential Address to Section A).

Prof. G. Hickling: "Some Geological Aspects of Recent Research on Coal" (Presidential Address to Section C).

Prof. J. G. Smith: "Economic Nationalism and Foreign Trade" (Presidential Address to Section F).

Dr. Ll. Wynn Jones: "Personality and Age" (Presidential Address to Section J).

Dr. A. W. Pickard-Cambridge: "Education and Freedom" (Presidential Address to Section L).

At 2 p.m.—Conference of Delegates of Corresponding Societies. Prof. P. G. H. Boswell: "Preservation of Sites of Scientific Interest in Town and Country Planning" (Presidential Address).

At 8.15 p.m. Dr. S. J. Davies: "Diesel Engines and Coastal Shipping" (Agricultural Hall Assembly Room).

The Changeful Earth

THE address of Prof. W. W. Watts, F.R.S., this year's president of the British Association, appears in the supplement to the present number of NATURE. In the "Form, Drift, and Rhythm of the Continents", he has a very big subject, covering many topics that are debatable, for geology is a highly controversial subject when we get down to principles, and is likely to remain so for a long time to come.

Uniformitarianism is referred to briefly, and the help that Darwin admits he obtained from a consideration of this and kindred topics as set forth by Lyell is mentioned; but is it not going too far to say that Lyell only just missed the discovery of organic evolution? If he only just missed it, why was his recognition of its truth so tardy? Is it permissible to attribute heroism to Lyell because in the long run, and very reluctantly, he admitted its truth? In any event, the principle of uniformitarianism, while no doubt essentially sound, should be applied with some caution; for it is not difficult to believe that dynamic agencies acted much more impetuously on the earth's crust during the early stages of its history than they did during later times, and even during later times there are some results the explanation of which seem to call for an occasional display of impetuous dynamic agencies. Later on in his address, in the portion dealing with the nature of the interior of the earth, Prof. Watts acknowledges this, and arrives at a view which "is neither strictly uniformitarian nor strictly catastrophic, but takes the best from each hypothesis". The important fact to note is, however, as he points out, that taking the earth as a whole "the chain of life has never snapped", and organic evolution has proceeded continuously throughout the traceable history of the earth's crust.

In a brief outline of the geological story of the earth, the idea of rhythm is developed, involving the alternation of periods of land growth with periods of marine transgression, as advocated by Suess. To account for this rhythm, Prof. Watts refers to the theory of the earth's contraction by loss of heat, and he seems to regard this as the factor of prime importance in the explanation of mountain growth and rock folding. He points out, however, that some geologists have found this theory inadequate, because in their opinion it is unable to account for the large amount of compression involved in mountain building.

A consideration of the age of the earth gives Prof. Watts an opportunity of emphasising the importance of radioactivity in the earth's crust as a hidden reserve from which it replenishes the supply of heat it requires to make good the losses sustained by radiation, and of remarking on the ample sufficiency of this reserve to explain the great age of the earth. Here he states Joly's view that, as a result of radioactivity, dissipation of the earth's energy, although continuous, proceeds by a process of pulsation, and that this furnishes the explanation required to account for the rhythmic alternation of land growth and marine transgression already referred to. Prof. Watts is apparently a strong supporter of this view, for he assures us that, "As Darwin found the missing word for Lyell, so Joly in his theory of thermal cycles has indicated the direction of search for a mechanism to actuate the rhythm of Suess". Here we are in some difficulty, for in connexion with

this view it is suggested that continental masses are embedded in a substratum of denser rock matter, in which they float as do icebergs on water; and whether we believe this or not, we may reasonably doubt if it can be harmonised with the theory that rock folding and mountain building are the outcome of tangential compression due to loss of heat and consequent contraction of the earth's mass.

The portions of Prof. Watts's address dealing with the Atlantic and Pacific Oceans, and with continental drift, will be read with much interest by geologists, as this subject has been widely discussed in recent years. In dealing with it, Prof. Watts contents himself with a recital of published pros and cons, showing on the whole an affectionate regard for the pros, while leaving us with the impression that he has not quite made up his mind. He points out the structural contrasts between the shore lands of the Atlantic and those of the Pacific. He further mentions the rough parallelism between the two coast lines of the Atlantic, the close resemblances between the structure, rocks and fossils in the land areas bordering the two coasts, and various other features that have been brought into the account to support the hypothesis of continental drift, which Wegener did so much to popularise some years ago, and which on that account usually carries his name. According to this hypothesis, the above-mentioned Atlantic features are to be explained partly by the view already mentioned as supported by Joly, that continental masses float in a denser substratum like icebergs on water; and partly by the view that the Atlantic margins represent one of many fractures which dissected what was formerly one vast continental mass, and that the separate masses thus defined by fractures have since drifted apart as a result of differential rotation or some other cause. To satisfy those who have difficulty in accounting for the Western Cordilleras of the Americas, the advocates of continental drift explain that these are due to the piling up of rock masses against obstacles which have arrested the drifting movement, and the same rather shabby explanation is applied to the origin of the Himalaya and some other mountain masses.

Prof. Watts no doubt sees many difficulties in the way of accepting this hypothesis, although, from the support he gives to Joly's views, one would expect him to be an out-and-out supporter of it. He realises, however, that its basis is purely speculative, for he tells us that the only way to settle it is by making more exact and longer-period measurements of longitude and latitude than have hitherto been possible. Unfortunately, however, such variations as have been recorded are, we are told, well within the limits of error involved in the observations. Indeed, pending the establishment of a stronger groundwork of fact for this hypothesis, the older theory of foundering subsidence for the origin of the Atlantic, and ordinary tangential compression for the origin of mountains, seems decidedly preferable.

In a concluding section on the evolution of life on the earth, reference is made to changing physical and biological influences as quickening or checking competition, and thus affecting the rate of evolution. The case of the grasses receives special mention. The geological date for the appearance of this important group of plants is given as early Tertiary (probably late Eocene) times. Not only is this group of plants important as a source of wheat and many other foodstuffs on which mankind depends directly; they are also of importance indirectly as nourishers of numerous kinds of animals that serve as human food. The appearance of these grasses was a factor of immense importance during Tertiary and later times in stimulating the evolution of the vertebrates, including man, whose brain, Prof. Watts tells us, is of all the wonders of the known universe the most wonderful, "the most intricate and efficient mechanism ever devised, . . . capable of inspiring and ruling great masses of mankind".

A lofty note is struck in the last paragraph of this interesting address, which spreads before us such a varied feast of scientific thought concerning the earth on which we live. In the concluding six words of this last paragraph, Prof. Watts speaks of "the golden ages that have gone". He almost persuades us to think, however, that "the best is yet to be, the last of things for which the first was made"; for he assures us that we are still far from the end of the mighty purpose that shows itself in the evolution of life on the earth, and that we can look forward with confidence to a further advance. Fortified by this assurance, we may reasonably hope that *Homo sapiens*, the wonder-brained creature that proudly labels itself "heir of all the ages, in the foremost files of time", will, in the coming years if not in the immediate future, show by wise governance in world affairs that it is worthy of the great earthly heritage into which it has entered.

Man Conquers the Desert

The Desert Fayum

By G. Caton-Thompson and E. W. Gardner. Vol. 1. Pp. xiv+167. Vol. 2. Pp. vii+114 plates. (London: Royal Anthropological Institute of Great Britain and Ireland, 1934.) 30*s*. net.

THESE two handsome volumes present with a wealth of detailed evidence the results of three seasons' pioneer work in the arid desert of the Fayum depression. Regions, previously traversed only by camels or donkeys, had to be opened up to motor-cars; water had to be supplied to gangs of native excavators encamped twenty-five or more miles from the nearest spring; the intrigues of other expeditions had to be circumvented. In the face of these obstacles the authors completed a contoured map of 100 square miles within the depression, and an archæological and geological survey of a much wider area.

The geological conclusions of the expedition have been published already in specialist journals. The present book merely notes the subsequent confirmation by the Geological Survey of Egypt of Miss Gardner's figure for the maximum level of the Pleistocene lake and of the existence of a rock sill across the Hawara channel that finally disposes of a rival theory of the origin of the lake: otherwise, ignoring controversy, the conclusions are just restated here. In Pleistocene times a great lake filled the depression to 115 ft. above sea-level; it then dried up almost completely, to be succeeded after an indefinite interval by a Neolithic lake with its highest beach at 59 ft.; the second lake contracted by stages until its strand lay 7 ft. below sea-level in Old Kingdom times and afterwards shrank even faster towards the present Birket Qarun. The pauses in the contraction of the lake must be due to increased rainfall, but nothing like a 'pluvial period' is admitted in holocene times. Maps and tables show how the archæological remains must be correlated with the several stages in the contraction of the Neolithic lake. Thus the laborious levelling and plotting, epitomised in these charts, serve to establish the relative ages of the human cultures to the description of which the bulk of the text is devoted.

The co-operation of several sciences secured to the expedition three outstanding triumphs. First, it provided the solution to the problem which first attracted Miss Caton-Thompson to the Fayum —the classification of the remarkable flint tools collected there and the determination of their relative age and cultural status. The makers of the oldest—Neolithic *A*—flints lived along the shores of a lake, 180 ft. above the modern lake-shore, and were allied to, and probably contemporary with, the oldest neolithic peoples discovered (after the first seasons' work in the Fayum) in the Nile Valley at Tasa and on the edge of the Delta at Merimde. With the discovery of their makers' actual settlements, silos, grains and household equipment, the long-familiar flints can be seen as marks of what is perhaps the oldest food-producing community yet known to archæology. Meticulous excavation, followed here by exhaustive publication, has yielded a vivid picture of this early phase of civilised life, while its scientific value is enhanced by expert reports on grains, animal bones and other materials.

To British prehistorians, the Fayum culture should appeal particularly, since Menghin has shown that our oldest neolithic culture is ultimately sprung from the same stock. On its origins the authors are wisely non-committal. (One reason for their reluctance to admit an eastern origin will have been removed by Mallowan's discovery of emmer nearly as early in Assyria.) In any event, though the Fayum *A* culture is the best illustration of a critical stage in man's progress, it is not the starting point of the new economy; the barley from the neolithic granaries, for example, is almost as far removed from its wild ancestor as is that grown in Egypt to-day. The primary stages in the plant's domestication must therefore be sought in a still remoter past.

Nor does the Fayum reveal any development of its oldest culture. The next phase, when the lake had sunk 20 ft., witnesses rather a degeneration. To it belong microlithic tools which on old typologies would have been classed as 'pre-neolithic'. The first advance comes with the Egyptians of the Old Kingdom. The expedition discovered gypsum and dolerite quarries of that age and forgotten roads leading across the desert to the Pyramids—a triumph nearly as dramatic as the recognition of the older neolithic culture. It adds materially to our appreciation of the industrial organisation of the Old Kingdom. The authors found a village of more than two hundred hut-circles (quite like those so familiar in Britain) in which the gypsum workers were housed, no less than 3,233 unfinished vases and piles of flint-nodules—the raw material for quarryman's picks. The collection and transportation of these heavy flints from a considerable distance must itself have employed a multitude of labourers. The discovery in the village of a rope

of undoubted camel hair and of horn-cores belonging probably to *Bos brachyceros* should be noted by zoologists, since both animals are reputedly foreign to the early holocene of Africa.

The expedition's third triumph was the identification of a Ptolemaic irrigation system. The canals had been completely masked by sand, but were revealed to Miss Caton-Thompson's expert vision by seedlings that, after a shower, sprouted most luxuriantly along the line of the old channels. Excavation defined the character of the channels, fixed their date and showed that they had rendered possible the cultivation of vines and date-palms on this now treeless waste. In this instance, archæology may prove to have a positive economic value.

V. GORDON CHILDE.

Philosophy of Modern Physics

(1) Science and the Human Temperament
By Prof. Erwin Schrödinger. Translated, and with a Biographical Introduction, by James Murphy. Pp. 154. (London: George Allen and Unwin, Ltd., 1935.) 7*s.* 6*d.* net.

(2) Science and the Human Temperament
By Prof. Erwin Schrödinger. Translated by Dr. James Murphy and W. H. Johnston. Pp. 192. (New York: W. W. Norton and Co., Inc., 1935.) 2.50 dollars.

THESE two books are identical but that the one published in America has an error on the title page, where the author is wrongly described as "formerly" professor in Berlin.

The essays here published together were produced at various times for various occasions, but they are all philosophical discussions of modern physical theory designed for the general public more than for the professional physicist. The essays are all most readable and written in a lively and even provocative manner. The last of them is Prof. Schrödinger's Nobel Prize lecture and contains a simple account of the ideas underlying his well-known, if little understood, wave theory of matter. The author explains that, just as light for some purposes can be treated as consisting of rays moving in straight lines, for others it can be treated as a system of transverse waves, which can spread round obstacles; so also the electron for some purposes can be treated as a particle, for others as a wave system. The difficulties underlying the theory are essentially those that arise when we try to translate concepts that have been developed to deal with the familiar large-scale operations of Nature into terms which are applicable to operations on the smallest scale of the elementary units. The older physicists assumed that no translating was needed and that their concepts applied through and through, although they were anthropomorphic in the sense of being derived from the ordinary mechanical arts.

The other essays deal in the main with two other difficulties of a similar kind. One of these has now been apparent for a long time, ever since it was realised that the laws which are found by observation to describe the behaviour of gases, the transfer of heat, the progress of chemical reactions, and so on, are based upon complete chaos of the individual particles making up the things that are actually handled experimentally. The regularities appear only because the individual particles are handled in very large numbers, just as insurance companies remain solvent because large numbers of people take out policies. The other is the more novel Uncertainty Principle of Heisenberg: the assertion that there is necessarily a rigid limit to the accuracy of observation, a limit determined by a natural constant. Hitherto it had been assumed that—in principle at any rate—observations could be made with any degree of accuracy; though now, after the event, it is easy to see that the assumption never had a leg to stand on. Prof. Schrödinger points out that even if this principle introduces a new sort of indeterminism, classical theory was not so strictly deterministic as has been popularly supposed. You can never specify more about the motion of an object than that at t_0 it is at p_0, and after a finite interval, at t_1 it is at p_1, and so on. At least two observations are needed, and all observations are limited by the fact that the scales of instruments have a finite number of divisions at finite intervals.

The writings of Eddington and Jeans have popularised the notion that modern physical theory leads inevitably to some kind of 'Idealism' similar to that of Berkeley. Prof. Schrödinger's treatment provides no warrant for this view, and on this point we would emphatically contradict the suggestion Mr. Murphy makes in his introduction. Mr. Murphy and the other translator have, however, done their translating very well; there is none of the awkwardness so often apparent.

A. D. R.

Physiology and Pathology of Internal Secretion

The Diseases of the Endocrine Glands

By Dr. Hermann Zondek. Third edition, revised and enlarged, translated by Dr. Carl Prausnitz. Pp. xi+492. (London: Edward Arnold and Co., 1935.) 40*s*. net.

THE addition of yet another volume to works on diseases of the endocrine glands can only fill the expert reader with dismay, unless such a work has outstanding characters. The work at present under review, from the theoretical point of view, has everything against it; for it deals mainly with the pathology of the endocrine glands, is written by an author well known for very strong personal views, and it is a translation from the German. It may be stated at the outset that despite these difficulties the work forms a most valuable addition to the literature of this subject. Dr. Hermann Zondek is well known as a member of the distinguished scientific family of which his brother, Prof. Bernard Zondek, has contributed perhaps some of the most striking developments of modern endocrinology.

The volume is divided into two parts, part one being concerned with the general physiological and biochemical principles of the glands and internal secretions, and part two solely with the pathological changes. A good historical review is given in part one, the functions of the hormones, their mode of action and the question of specificity are carefully considered and the site of action in the body briefly discussed.

The section dealing with the actual chemistry and physiology of the hormones is rather disappointing. Thus, a more detailed description of the reasons for the adoption of the Harington formula for thyroxine should have been given. The summary of the present position of our knowledge of the hormones of the anterior and posterior lobes of the pituitary gland is very good, but one would have liked more details of the chemical properties of these substances. Again, it is unfortunate that Dr. Zondek has not gone more fully into the question of the chemistry of the male and female sex hormones. For example, the very important recent developments whereby sex hormones may be obtained as degradation products of certain sterols is not made at all clear. It is, of course, difficult for the author of such a volume to know what to include, since the subject is so vast; but for future editions we would suggest that more chemical details are given, since these are the basic facts of our knowledge of the endocrine glands.

In the special part of this work, Chapter xii is concerned with Graves' disease, and is a very good summary of our present position. There can be no doubt that the greater part of this description will be new to chemical and clinical readers. The whole subject of hyper- and hypo-thyroidism is considered from a hormonal aspect. The description of the treatment of hyper-thyroidism is particularly interesting, although all will not agree with some of Dr. Zondek's remarks; for example, on p. 169 he implies that there is no use whatsoever for digitalis in Graves' disease. Other chapters deal adequately with the subjects of myxodæma, cretinism and endemic goitre.

There is an excellent chapter on obesity. Dr. Zondek very wisely points out that the fundamental consideration in the problem of obesity is the excess of intake over output. The endocrine glands can only accentuate or diminish this fundamental consideration. Many writers on endocrinology tend to give the impression that even the first law of thermodynamics can be defied. Various types of obesity are dealt with, such as Frölich's syndrome, Dercums' disease and similar conditions.

The work is undoubtedly one of very great value. One may perhaps be irritated by the writer's emphasis of his opinion, but perhaps it is this factor that gives the book that freshness which is absent from most works of this kind. It is to be hoped that it will be read extensively by physicians and particularly by gynæcologists and obstetricians, who seem to be unmoved by the truly amazing progress made in their subject by endocrinologists. They have been presented with gift after gift, such for example as the Aschheim-Zondek reaction, but they appear to pay little attention to this branch of their work.

The book is well produced, with good and well-selected illustrations. The work differs from most translations in that the casual reader would not realise it is a translation, and this is perhaps the greatest compliment one could pay to Dr. Prausnitz. Some of his translations are extremely apposite; for example, "Mastfettsucht" is translated simply as "overfeeding", whereas "Luxuskonsumption" is "alimentary extravagance". Dr. Zondek is to be congratulated on producing one of the best books on the subject and Dr. Prausnitz on supplying the perfect translation.

Sir Ray Lankester as Archæologist

Prehistoric Archæology and Sir Ray Lankester
By J. Reid Moir. Pp. viii+160. (Ipswich: Norman Adlard and Co., Ltd., 1935.) 7*s.* 6*d.*

SIR RAY LANKESTER was one of the most versatile and inspiring scientific men of his generation. His own researches in biology and geology were remarkably varied, but his active interest in the work of others was still more comprehensive. He watched each new development and did not hesitate to form his own opinions on the evidence produced. He frequently entered discussions on problems outside his immediate sphere, and helped to illuminate them by his keen appreciation of their nature and possible mode of treatment.

Among other problems which interested Lankester were those of prehistoric archæology. As a young man he visited Abbeville and Boucher de Perthes, who gave him examples of the palæolithic flint implements which were then being discovered in the valley of the Somme. In his later years, from 1910 onwards, he followed with close attention the researches of Mr. J. Reid Moir, who was finding still older and more primitive flint implements in the bone bed at the base of the Pliocene "Red Crag" in Suffolk. In 1911 he described Mr. Reid Moir's new implements in a paper read before the Royal Society, and gave to them the now familiar name of 'rostro-carinates'. In subsequent years he continued to make further contributions to the subject.

From 1910 until his death in 1929, Sir Ray Lankester wrote many letters to Mr. Reid Moir during the progress of his researches and publications. They are full of characteristic comments and helpful suggestions, and the most important parts of them are now printed with a connecting narrative by Mr. Reid Moir in the small volume before us. Some relate to the Red Crag and its basement bed, which Lankester studied and described so long ago as the years 1865–70. Some give hints for the study of the fracture and patination of flints; others offer excellent advice on the writing of scientific papers. Some deal with current researches on fossil man and his handiwork outside East Anglia. They tell a most interesting story, which we commend both to archæologists and to all who wish to see science in the making.

A. S. W.

Tables of the Complete and Incomplete Elliptic Integrals
Reissued from Tome 2 of Legendre's "Traité des Fonctions Elliptiques", Paris 1825. With an Introduction by Karl Pearson. Pp. xliii+94. (London: *Biometrika* Office, University College, 1934.) 12*s.* 6*d.* net.

COPIES of Legendre's classical work, "Traité des Fonctions Elliptiques", published in Paris in 1825, have now become very scarce, with a consequent rise in price. To the mathematician, this has considerably diminished the accessibility of the fundamental tables of the complete and incomplete elliptic integrals E and F, which were contained in Volume 2 of the treatise. By means of the photographic process, however, it has now been possible to republish the tables, and the present volume is the result. Not the least valuable part of the book is the excellent introduction written by Prof. Karl Pearson. Here we have 39 pages devoted to a lucid explanation of the tables and their use. Several interesting diagrams are shown and a beautiful autographed portrait of Legendre is included. As the tables are a photographic reproduction, the book is larger than usual, but all those whose work necessitates the use of the tables will be grateful to the *Biometrika* Office for issuing such a valuable work of reference at so reasonable a price.

Gasentladungstabellen:
Tabellen, Formeln und Kurven zur Physik und Technik der Elektronen und Ionen. Von M. Knoll, F. Ollendorff und R. Rompe. Unter Mitarbeit von A. Roggendorf. Pp. x+171. (Berlin: Julius Springer, 1935.) 29 gold marks.

A VERY considerable proportion of modern physics is concerned with electrical phenomena in more or less evacuated vessels. The worker in this general field, whether his special interest be in thermionics, in light-sources for spectroscopy, or in any other of its many branches, needs at one time or another information about the properties of a vast number of things. He may require the ionisation potential of cæsium, the vapour pressure of cadmium at 100° C., the specific resistance of molybdenum at 1,000° C., or the relative rates of sputtering of aluminium and iron cathodes in a hydrogen discharge. All these data, and hundreds more, can be found in this very useful book, which contains in graphical or tabular form an immense amount of quantitative information of value to workers on electrical discharges.

The authors have been commendably careful in making clear the units in which the various quantities are measured, and the sources from which the information has been obtained. The index, which is of the greatest importance in a book of this kind, seems to be quite adequate.

A Bibliography of Sir Oliver Lodge, F.R.S.

Compiled by Theodore Besterman. Pp. xiv+220. (London: Oxford University Press, 1935.) 21*s.* net.

SIR OLIVER LODGE has for many years been a clear and prolific writer on many subjects, and Mr. Besterman has collected a list of 1,156 books, pamphlets, articles, letters, notes, etc., in scientific, technical and other journals and books written by Sir Oliver in the past sixty years. Of these, 247 relate to electricity and wireless communication, 54 to questions concerning the ether, 289 to other scientific subjects, 70 to psychical research in general, 73 to survival after death, 64 to education, 170 to philosophy and religion, 118 are biographical or are reviews of or prefaces to books by other authors and 71 are on miscellaneous subjects. An index of 23 pages, which distinguishes typographically between books and pamphlets on one hand and contributions to periodicals on the other, facilitates reference to the book.

In the preface, Sir Oliver has added some further information as to his early demonstration of wireless signalling at the meeting of the British Association at Oxford in 1894, and the developments which followed. The book is well printed, and the portrait of Sir Oliver which forms the frontispiece is very good and shows him in a characteristic attitude. An absence of cross references throughout the book makes it difficult to follow the course of discussions on psychical or religious subjects between Sir Oliver and his critics. Sometimes a reply is tabulated without the criticism, at others the criticism without a reply, as for example, Sir Herbert Stephen's criticism of "Raymond" on p. 111. No hint is given that Prof. Armstrong's article, xxi p. 191, entitled "Sir Oliver Lodge, Intolerant, Infallible", is the fourth member of a quartette, the others being Sir Oliver dcvi p. 102, Sir Ray Lankester xxix p. 191, Sir Oliver dcxi, p. 103. The roman numerals for articles throughout the book, as for example, "Science and Psychical Research dcccexlviii", instead of 948, p. 215, of the index, detract considerably from the ease of reference to the Bibliography.

The Origins of Religion

By Prof. Rafael Karsten. Pp. viii+328. (London: Kegan Paul and Co., Ltd., 1935.) 12*s.* 6*d.* net.

PROF. KARSTEN, in formulating his theories of the origins of primitive religion, is in a position to draw upon an extensive acquaintance with the beliefs of backward peoples, especially in South America, at first hand. He is thus able to meet the more serious critics of the comparative method in the study of religion on their own ground, when they impute neglect or ignorance of the context as a fatal flaw in the argument. On the other hand, although he himself maintains the predominance of animism and ancestor worship as formative influences in the religious side of man's cultural development, he points out that those who have followed Tylor and Spencer have frequently been entirely uncritical in the use of authorities upon whose evidence they have based the evolutionary view of the growth of religion.

Prof. Karsten is to be regarded as in the main an evolutionist, though he is no upholder of the crude view of a unilateral line of development. On the other hand, he is ready to recognise that diffusion and *kulturkreise* are not to be ruled out, and that they, too, have played their part. Preanimism or animatism, however, finds no favour as a precedent to animism, and is regarded as late and sophisticated.

The book is an excellent and well-balanced review of current theory and reinterpretation of the evidence in the light of personal first-hand knowledge. Its value is enhanced by the use the author has made of evidence afforded by the beliefs of Finno-Ugrian peoples which, owing to difficulties of language, are not generally accessible.

Terrains, roches et fossiles de la Belgique

Par Eug. Maillieux. Deuxième édition, revue et augmentée. Pp. 217. (Bruxelles: Musée royal d'Histoire naturelle de Belgique, 1933.) 6 belgas.

THIS work is an excellent summary of the present state of knowledge of the stratigraphical geology and palæontology of Belgium, and while invaluable to geologists, sufficient explanatory matter is given to make the book of use to readers with only a small knowledge of the subject. With the exception of the Cambrian system, the range of formations is almost as extensive as in the British Isles, and the deposits, in the main, resemble those of these islands. The palæontological record really starts with the Tremadocian, there being no definite evidence to show whether earlier formations are of Cambrian or pre-Cambrian age. Three maps show the outcrops of Palæozoic, Mesozoic and Tertiary formations respectively, from which it is seen that the Mesozoic deposits occupy a relatively small area, the Palæozoic form most of the southern part of the country, and the Tertiary the northern part. Intrusive and extrusive igneous rocks are of little importance.

The palæontology of each system and its divisions are lucidly described and illustrated by numerous figures. Interest is given to the stratigraphical facts by an account of the conditions under which the deposits were formed and of the geographical changes which took place during each period. A new section across the Ardennes by Prof. F. Kaisin is welcome.

Opera hactenus inedita Rogeri Baconi

Fasc. 12: Questiones supra librum de Causis. Nunc primum edidit Robert Steele, collaborante Ferdinand M. Delorme. Accedit Liber de Causis a Roberto Steele. Pp. xxiv+196. (Oxford: Clarendon Press; London: Oxford University Press, 1935.) 17*s.* 6*d.* net.

THIS excellent edition of Bacon's commentary on the "Liber de Causis" brings nearer to completion the publication of the works of the erudite Franciscan friar of the Middle Ages. The thesis and the commentary are printed separately, following the method used by medieval writers. The history of the MSS. used for this edition is given by Mr. Steele in a comprehensive introduction. The work deals with some fundamental points of ontology, such as being, substance, cause and the intellect. T. G.

Robert Hooke and his Contemporaries

"DR. ROBERT HOOKE is generally allowed to have been one of the greatest promoters of Experimental Natural Knowledge, as well as Ornaments of the seventeenth century, so fruitful of great genius." With suchlike words Richard Waller begins his introduction to the "Posthumous Works", and the judgment still holds good. Nevertheless, our information as to Hooke's life and character has hitherto been comparatively meagre, for Ward's "Life", and most of what has besides been written of him, derives from Waller's account, and Waller apparently had little personal knowledge of Hooke or his intimates, since he states that his main authorities are Hooke's brief biographical notes and the "Journals" of the Royal Society. It is typical that Hooke is one of the few great men of science of whom no portrait is available—possibly the only one, for even of Cavendish we have the well-known sketch prefixed to George Wilson's "Life" and the "Scientific Papers". Hard judgments have been pronounced on him, without, perhaps, much trouble taken about that understanding which is said to lead to comprehensive pardon. The publication* of Hooke's diary for 1672–80, now in the possession of the Corporation of the City of London, at least affords us some direct evidence as to his character and mode of life.

This Diary covers the period of the "Cutlerian Lectures" and "Philosophical Collections". Hooke was thirty-seven years old when he started it, and had already published the "Micrographia" and made some of his most important improvements in instruments, including the first Gregorian telescope with a pierced objective mirror, but was still in his scientific prime. The diary consists of brief entries in staccato style, as can best be shown by a typical entry.

"Monday June 15th Rose at 4. Mr. Amhurst desired a meeting this day at 3. Tryd helioscope by reflection. Hurt my eye much—prosecuted Hevelius. Was at Lord Mayors and coffee house with Sir Ch. Wren. Lord pleased with accounts. Oliver a Rascall. Dean of Paules angry. At Garaways. Met Mr. Amhurst, 1 Guinny. View in Fleet Street 10sh. At Mr. Tompions".

It might be thought that this kind of thing would soon pall, but one reader at least has found it fascinating. The "Cutlerian Lectures", the "Philosophical Collection", and Birch's "History of the Royal Society" go far to elucidate obscurities and amplify allusions, while the Diary makes the formal records extraordinarily vivid and personal.

For general interest this Diary does not, of course, challenge comparison with Pepys, but we must respectfully dissent from the judgment implied in the charming words of introduction by the honoured president of the Royal Society, Sir Frederick Gowland Hopkins, that the difference in style is partly attributable to the fact that Hooke's diary was meant for himself alone, while Pepys had his eye on eventual readers. Surely the fact that Pepys, who used a special secret shorthand, was essentially a gossip and a man about town, while Hooke was a man whose interests were concentrated on pure and applied science, and who had no interest in public affairs and society, as distinct from The Society, supplies a sufficient reason. It is much to be regretted that the two diaries do not overlap in time, Pepys's concluding three years before Hooke's starts, but it is amusing to note that the two men, of such different temperaments, met and liked one another. There are several references to Hooke in Pepys, the first speaking of "Mr. Hooke, who is the most, and promises the least, of any man in the world that ever I saw". Elsewhere we read:

"Discoursed with Mr. Hooke about the nature of sounds and he did make me understand the nature of musicall sounds made by strings, mighty prettily; and he told me that having come to a certain number of vibrations proper to make any tone, he is able to tell how many strokes a fly makes with her wings (those flies that hum in their flying) by the note that it answers to in musique, during their flying. That, I suppose, is a little too much refined; but his discourse in general of sound was mighty fine".

Thus the president-to-be (1684–86) of the Royal Society. On the other hand Hooke, in his briefer style, writes: "I was twise with Mr. Pepys who was very civil and kind", and even if he says later "Mr. Pepys master of the Trinity House made a long speech to no great purpose", it is only his way of stating that it was a "little too much refined".

What does the Diary tell us? We premise that it is obviously a truthful personal record, written without any thought of possible readers. Hooke sets down with a symbol every passage—and at one time they were frequent—with his mistress Nell Young and with her successors, and a host of pitiful details of his troubled health. Entries like

* The Diary of Robert Hooke, M.A., M.D., F.R.S., 1672–1680. Transcribed from the Original in the possession of the Corporation of the City of London (Guildhall Library). Edited by Henry W. Robinson and Walter Adams. Pp. xxviii+527+8 plates. (London: Taylor and Francis, 1935.) 25s.

"Drunk. Promised to pay whatever I signed to be paid" show that he spared himself no less than others in his directness. The first thing that stands out clearly is that Hooke was a sick man, trying all the time with medicine and diet to win a little ease. He was troubled constantly with what appears to have been a form of catarrh in his nose, with terrible headaches, with vomiting, with giddiness, with sleeplessness, with indigestion in various forms, and with fearful dreams—possibly also with worms, for he frequently took what he calls hagiox, which is probably hagiospermum, that is, santonin, which nowadays, at any rate, is only used for that trouble. Nevertheless, only occasionally was he too ill to work—"Ill all day, miserere mei deus". When anything agreed with him, or he slept, he thought it worth noting. "Eat nuts and brandy. Agreed well, and slept". "Slept well. Deo Gratias". The medicines which he took almost daily make a formidable list.*

There is some excuse, then, for Hooke's reputed ill-temper. Not only, however, was he without ease and sleep ; it is clear that he was prodigiously overworked. "The indefatigable Hooke", Weld may well call him. What is sometimes forgotten is that Hooke was a considerable architect, so much so that the College of Physicians in Warwick Lane has been attributed to Wren, although it appears that it was Hooke's. In any event, he was the architect for Bethlehem Hospital, to which very many entries refer, and he appears to have been responsible for the urn on the Monument, which gave some trouble. He designed private houses for many individuals mentioned in the Diary. He had been appointed City Surveyor in 1666, in which capacity he was assisting Sir Christopher Wren all through the period of the Diary, so that there is scarcely a page on which Sir Christopher is not mentioned. There are frequent records of his being with Sir Christopher and, incidentally, with Robert Boyle, Sir J. Hoskins, and other famous men, a circumstance to be noted in connexion with Thomas Molyneux's accusation that Hooke was "the most ill-natured, conceited man in the world, hated and despised by most of the Royal Society". Strange that he should afterwards have become secretary of the Society! The truth is probably that he was impatient with fools, and ill-tempered at times, especially when he thought himself slighted. As, however, he seems to have been on good terms with most of the first-class intellects of the time —Wren, Boyle, Ent, Glisson, Petty, Aubrey and a host of others—and throughout the Diary we find him playing chess with Haak, and in the company of Abraham Hill, Daniel Whistler, Halley, and many others whose names occur over and over again as his coffee-house companions, he cannot have been so difficult as it pleased his enemies to make out. Sydenham invited Hooke to stay with him for six weeks.

If it is clear that Hooke was sharp-tempered, it is equally clear that in most cases he bore no malice. He discharged Nell Young from his service in 1673, but she continued to make his clothes and they visited one another, and although there was a quarrel in 1676, "Paid Nell for suit 6s8d besides the full of her bill 16s6d never more to do with her", within a few weeks we find "At Nell's", which thereafter occurs at intervals, as usual. Occasionally he rails at Tompion, who appears to have been slow and often behind his time, "a slug", "a rascall", but they continue to work together through the Diary, and no doubt knew one another's worth and idiosyncracies perfectly well. Even in the case of Oldenburg there is no unkind entry at his death, and Hevelius's fire is referred to sympathetically.

The people whom Hooke consistently stigmatises as rogues—Oldenburg ("a lying dog", "treacherous and a villain") and Sir John Cutler ("a villain", "a cheating knave", "Sir Stingy"—I presume that this is Sir John) appear to have done much to earn his just indignation. Oldenburg first incurs censure for not registering things brought into the Society, and there are references to his not entering experiments long before the controversy over the application of the spiral spring to the balance wheel of watches. This dispute over the balance wheel seems to have upset Hooke more than any of his other troubles. We find the entry "Saw the Lying Dog Oldenburg's *Transactions*. Resolved to quit all employments and to seek my health". (Oldenburg was responsible for the *Transactions*, which were in a sense his property, as he received all profits on the sales.) It is often held that Hooke was in the wrong, and that Oldenburg was a harmless and devoted servant of the Society, as, indeed, he induced the Society to say. It is, however, recorded of him that he "had a peculiar temper, which prevented him agreeing well with others", while at the same time he had had an early training in diplomacy which possibly rendered his approach to the truth somewhat less direct than Hooke's.

When it is remembered that Oldenburg had a financial interest in Huygens' watch, since Huygens had assigned him the patent rights, and his petition for a patent is on record, it is, perhaps, possible to believe that he was not completely unprejudiced. His statement that none of Hooke's early watches had succeeded seems to go beyond what he could have known, and it was distinctly in his own interest to make it. Hooke's account of his early

* Sir D'Arcy Power, to whom I referred this passage, very kindly tells me that there is no doubt that Hooke's headaches were due to a chronic inflammation of his frontal sinuses.

invention is true where we can check it, and it seems quite likely, in view of what we know, that he had, as he says, dropped the matter because of a very reasonable objection of his to a clause in the proposed agreement, to take it up again when he heard what Huygens had done. Thomas Thomson, in his "History of the Royal Society", refers to Hooke's character in the most censorious terms, and yet says in connexion with the balance spring, "Huygens has been considered as the author of this happy invention; but there is complete proof that Hooke anticipated him by about 14 years". Anyhow, Hooke's accusation that Oldenburg was "a traffiker in intelligence" seems absolutely justified. The Newton-Leibnitz controversy throws doubt on Oldenburg's discretion, and, in spite of his plaintive protests, when he was committed to the Tower, there are letters on record to show that he did meddle with political matters in them, as well as with scientific news. Sydenham, "universally recognised" according to the "Dictionary of National Biography", "as noble, modest and sincere" liked him as little as did Hooke, and I, for one, have the impression that he was an oblique, intriguing and toadying individual, jealous of Hooke's fame and earnings.

Sir John Cutler undoubtedly promised Hooke a yearly salary for lectures, which Hooke amply earned, and yet Sir John constantly evaded all attempts to make him pay it. He seems to have had a bad reputation. "Sir W. Petty" (a shrewd man if ever there was one) "told me that Sir J. Cutler would never pay me". Finally Hooke brought a Chancery suit against Sir John's heirs, in which he was successful. Waller quotes from a diary, no doubt the one in the British Museum, "In July 1696, being his Birth Day, his Chancery Suit for Sir John Cutler's salary, was determin'd for him, to his great satisfaction, which had made him very uneasy for several Years". It is not greatly to Hooke's discredit that he strongly resented this arrant attempt to bilk him, especially after his lectures had appeared in print with a handsome acknowledgment, in advance, of Sir John's bounty.

Another matter in which Hooke has incurred blame is the controversy with Hevelius about telescopic sights. Here there is no doubt that he was, objectively, in the right in every particular, and his estimate of the resolving power of the human eye, which he was the first to treat scientifically, is a very good one. All that he claims as advantages of telescopic sights has long since been established, and his defence against the strictures of Wallis and Molyneux is correct in manner and faultless in exposition and matter. What Waller says, that in his original "Animadversions", "he chanc'd to let slip some Expressions which, tho' possibly strictly true, could yet never be digested by Hevelius", is the most that can be urged against him. Hevelius, however, had slighted Hooke's original reasoned suggestion that he should use telescopic sights, so that a little warmth on Hooke's part is understandable. When the controversy was revived by Hevelius publishing "Annus Climactericus" in 1685, Hooke, at the Royal Society, "showed his experiments to prove the excellency of telescopic sights above plain ones, by comparing a direction by the eye with a radius of ten feet, with that of a telescope of eight inches; and it appeared to the satisfaction of all present that there was a very great advantage in the telescope".

Let us see, however, if we can find any direct contradiction of the popular view of Hooke's character in the Diary. Among other faults with which we find him charged is "extreme parsimoniousness" (Weld). On the other hand, the Diary shows him spending freely. He is always buying books, often at prices round about 25*s.*, a large sum in those days. His gifts to his niece Grace were generous: "This morning I gave Grace, Axes Stone Ring and speckled silk stockings and Ruby pendule" is but one of many entries. There are frequent records of small gifts to servants and messengers and of loans, which do not seem to have been repaid. He made extensive purchases of silks, and cloth, of wine and of brandy, and seems to have been always buying shoes. Incidentally, his use of the old term 'portoport' for port wine, of which he seems to have been fond, is much earlier than any given in the "New Oxford Dictionary". He frequented all the best taverns and coffee-houses and drank tea (the price of which was 15*s.* to 50*s.* a pound),* coffee and chocolate. He made gifts of tea and wine. One day he ate a pineapple "queen pine 2/-". He bought a hobby horse for Wren's son. He gave away copies of his books freely. These are only trifles, it may be said, but they are not rare. The general impression is that of a man who did not mind spending money on his friends and on himself—at the least the Diary makes it impossible to maintain that he was miserly.

Let us take another example. Baron Ernouf, author of the life of Denis Papin, says of his subject that he could not come to see Hooke, whom he terms "un de ces savants atrabilaires et soupçonneux dont l'espèce n'est pas perdue". Whether there was an occasion on which Hooke would not see Papin we cannot, of course, determine, but the Diary is full of entries of occasions on which he did, both when Papin visited him, and he visited Papin, so much so that under the name Papin in the index appears

* On January 16, 1679/80, Hooke "paid Chamberlain for tea, 25sh". A pound?

Passim. In July 1679, for example, they met almost daily. He seems to have done his best for the unfortunate Frenchman: "I treated with Broom and Car for Pappin's book but they agreed not". The only disparagement, if it may be so called, anywhere set down, is "Pappin ungrateful". Incidentally, a younger brother of Papin's appears, who is new to me.

The interest of the Diary for the history of science is great. It is full of observations of importance, many of which, but not all, so far as I can trace, were published later. Hooke records the hollowness of the flame of a candle: the extinction of flame by "air generated by corrosion or fermentation", "and how saturated air did the same thing", as well as many other interesting experiments on combustion: how a glass can vibrate in four, six or eight segments as shown by the movement of water in it.* We find the record of his experiment with the falling bullet, but not of his letter to Newton on the subject, though some of his important letters to Newton are noted. A curious entry refers to "the way to make aparition on the Stage by a concave cylinder", evidently a very early form of 'Pepper's ghost', and another example of Hooke's extraordinary inventiveness. Another anticipation is his observation of the curious forms sometimes shown by the rising sun—"saw the sun rise very elliptical the under side much flatter than the upper", with a drawing, and, just a year later, "the sun rose very ovall, red and indented". The earliest observations on this subject quoted by Pernter in his "Meteorologische Optik" are considerably later, namely from an unpublished manuscript of the younger Cassini, who was born in 1667.

All this time, Hooke was polishing mirrors, seeing Tompion about watches, and making instruments. There are references to the scotoscope, of which Pepys mentions an example:

"There comes also Mr. Reeve with a microscope and scotoscope. For the first I did give him £5-10, a great price, but a most curious bauble it is, and he says, as good, nay, the best he knows in England, and he makes out the best in the world. The other he gives me, and is of value; and a curious curiosity it is to look objects in a dark room with."

and to the otheometer, which I cannot find mentioned elsewhere, but which is evidently a name given to one of the many forms of barometer which Hooke invented. A matter of biographical interest is that in two separate instances there are records of Hooke giving away in the autumn copies of books which are dated the following year. There are also records of gilt copies, which must be very rare.

Reluctantly we must cease to quote from this book of manifold interests. One last note—for Mr. Dunne. On more than one occasion Hooke, who dreamt so much, speaks of prophetic dreams, as, for example, "Dreamt several things which came to pass the Day following", and again "Dream strangely fulfilled in Powis".

To produce this book has evidently been a labour of love for the editors, who have added an annotated list of the taverns and coffee-houses (some hundred and fifty of them!) mentioned by Hooke, and an excellent biographical index of getting on for two thousand names quoted in the Diary, nearly all of whom are Hooke's contemporaries. The transcription is, on the whole, excellent, but there are a few obvious errors, some of them amusing. "Eat candle, which agreed well" is not so surprising, if we suppose the word to have been "caudle"; and "cured by a felon in the neck" may well be a 'seton', if we remember the long esses.* "I wrote *myopitius gunamen*" is unlikely, if we remember that Hooke wrote a little tract called "myopibus juvamen". The "homocercle tadpoles in seed" are no doubt "homuncule", a term freely used for spermatozoa. Many of the authors and titles of foreign books and other foreign words have gone wrong: "Sutta anglicance" should clearly be "gutta anglicana": the "forces monantes" of Pardies' book should be "mouvantes" (possibly written "movantes" by Hooke) and I suspect that "Brooks' *Mathematical Jewell*" should be Blagrave's, for there is a book of this title by the latter author, of which a second version appeared in 1658, but have never heard of one by Brooks. Chizzell, in the index, should be Chiswell, who published most of the "Philosophical Collections". Slips like these, and others not quoted, are probably inevitable in a work of this length, and a few of them give the reader pleasant exercise in tracking them down. A word of praise must be spoken for the admirable illustrations, especially those of buildings planned by Hooke.

The publication of this Diary in a worthy form is an event for the history of science, and we hope that the encouragement shown by the Royal Society to its learned librarian, Mr. H. W. Robinson, upon whom the labour of the work has chiefly fallen, will incite him to further researches into the early history of the Society.

E. N. DA C. ANDRADE.

* See Waller: "Life". Hooke noted that to each figure corresponded "their particular and distinct Sounds or Notes", "the 4 and 8 were octaves and the 6 and 4 were fifths", observations which Tyndall assigns to Chladni.

* Felon was, of course, used as a term for a sore, Cf. Herrick.

"Where others love and praise my verses, still
Thy long black thumbnail marks them out for ill,
A fellon take it, or some whitflaw come
For to unslate or to untile that thumb".

Nevertheless, a deliberately produced felon is unlikely.

Characteristics of Violin Tone

THE scientific explanation of certain qualities of violin tone is still an unsolved problem of great complexity. When a copy of an old Italian violin has not the tone qualities of the original, it is very difficult to find in what details the unfaithfulness of the copy lies. No new scientific technique remains long unapplied to the problem, and the most recent results were included in Major C. E. S. Phillips' discourse bearing the above title delivered at the Royal Institution on May 31.

Some X-ray work done in America has indicated the importance of using, for the backs of violins, material in which the speed of sound is the same in all directions. A violin was shown in which the back was replaced with copper, which somewhat muted the tone, and another with a bakelite back in which the tone was almost unaffected by the change. A 'cello with a body made entirely of copper had a pleasant, woody tone.

A small microphone used as a searching device shows that the whole violin is thrown into vibration when the strings are bowed. Although it has been supposed that the chief function of the sound post is to convey vibrations from the front to the back plate, it has been found that if this post is removed and external pressure brought to bear upon the top plate above where the sound post

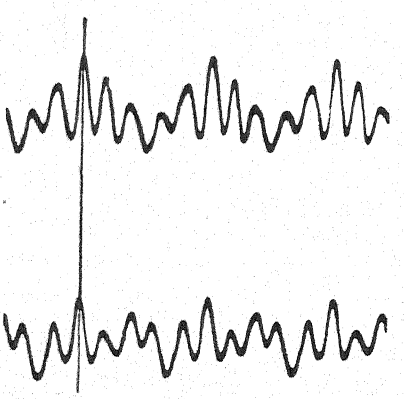

FIG. 1. Oscillograph records of tone of bowed *E* string of two Stradivari violins made in the same year, 1699. The lower record is from a 'long' pattern.

presses against it, the result is practically as good. Transillumination of two Stradivari violins shows that one with a higher arched front and back plate has been thinned more than one with a flatter front and back. The flatter top plate vibrates more easily under the pressure of the bridge than the one that is convex. The note heard on blowing across an 'f' hole of any Stradivari violin has a frequency of 256 vibrations per second.

Scientific examination of the varnish question may prevent much more of the haphazard mixing of all manner of gums and lacs dissolved in oil in attempts to make varnishes with magical qualities. Molecular size is an important factor

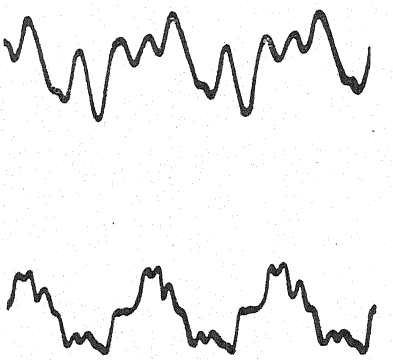

FIG. 2. Oscillograph records of tone of bowed *E* string without (above) and with mute (below).

affecting the penetration of the body of a varnish through the closely packed semi-permeable membranous cells of wood. If a varnish made by dissolving celluloid in acetone be applied to pine, the solvent will rapidly soak into the wood, leaving the celluloid behind. The early Cremona varnish as used by Stradivari or Guarneri entered the wood. Penetration would be helped by using a solvent of low surface tension on carefully dried wood, with thorough cleaning and special treatment of the surface to reduce the contact angle. The manner of application may be specially favourable under the atmospheric conditions of Italy. Terpenes obtained from the distillation of larch would have been known to Stradivari, and may have helped penetration when used to 'wet' the clean wood in a warm dry air before the application of a thin coat of an amber varnish.

An unvarnished violin soon loses some of its sonorous qualities, which are regained on varnishing. The tone of a newly varnished instrument is dull until the varnish dries thoroughly and hardens. The inside of a violin is seldom coated, and is free to absorb moisture from the air. Such absorption, which may amount to 30 gm., tends to stiffen the plate and may affect the tone. It is possible that the improvement of clearness of tone of violins with age may be explained by supposing that the small molecules of the body of the varnish slowly build themselves into larger groups, assuming a more closely-packed structure with increased rigidity. Examination by means of ultra-violet light serves to distinguish between

spirit and oil varnishes. Oil is present in all the 'Strads' so far examined by this means.

Since a violin is made up of seventy distinct parts, it would be surprising if the function of each were perfectly understood. For example, the tone of a violin without its back was found to preserve its main characteristic features. The result of the experimental removal of the sound post has been given already. The cuts and fretting of the bridge are not merely decorative. The rocking motion of the bridge in its own plane about the right foot as centre is important for fullness and quality of tone, which are but little affected when the effect of the rocking parallel to the strings is eliminated by reducing the feet to knife edges. Experiments in which the orientation of tiny steel rollers placed under the feet of the bridge was varied, were used to study this rocking motion of the bridge.

The latest attempt at the substitution of manufactured for grown fibres is in the use of artificial silk for horsehair of the violin bow. The viscose fibre retains the resin better than does the fine metal wire which is also in use for bows.

Microphone and cathode ray oscillograph have been used to obtain records of violin tone, and two examples are given in Figs. 1 and 2. During the discourse the famous 'Messie' Strad of 1760 was exhibited, and the intention of Mr. Arthur and Mr. Alfred Hill to present this unique instrument to the nation was announced. If, therefore, current scientific technique fails to solve all the problems of violin tone, future generations will have the problems handed to them in practical form.

Obituary

Prof. F. A. F. C. Went, For.Mem.R.S.

ON July 24 Prof. F. A. F. C. Went died at Wassenaar, near the Hague. He was born at Amsterdam on June 18, 1863, where he was also educated. He went to the University of Amsterdam in 1880, and worked under Hugo de Vries and also came in contact with Van 't Hoff and Van der Waals. After taking his doctorate in 1886 with a thesis entitled "De jongste toestanden der vacuolen" (The Youngest Stages of Vacuoles), Went spent some time in the laboratories of E. Strasburger (Bonn) and Ph. Van Tieghem (Paris), and then he made his first visit to Java as a fellow of the Buitenzorg Foundation.

Deeply impressed both by Nature in the tropics and also by the work and organisation of Melchior Treub, Went shortly after his return received a call to the Java sugar industry. For five years (1891–96) he was director of the West Java Sugar Experimental Station at Kagok. In this capacity, working with the late Dr. J. H. Wakker, he did very important work on the diseases of sugar cane. The results of their studies were published in their well-known book "De ziekten van het Suikerriet op Java" (The Diseases of Sugar Cane in Java, 1898). He also studied photosynthesis in the sugar cane and the formation of sucrose and other carbohydrates. Went, therefore, may be regarded as one of the pioneers of experimental stations in the Dutch East Indies, which later achieved a great reputation. His experience in Java also considerably influenced his later work. He inspired his students by his conviction that development of the Dutch Colonies should be based on scientific knowledge and a thorough investigation of the natural resources of the tropics.

Went succeeded Prof. N. W. P. Rauwenhoff in 1896 as professor of botany in the State University of Utrecht. In the first decade, he still taught the entire field of botany, but later special chairs were provided for taxonomy and plant geography, phytopathology and genetics. At first there were only a few students in biology, but gradually he attracted a large number of students. This involved much heavy teaching for a devoted and conscientious teacher such as he was, and it left him little time for his own researches. His investigations were restricted to some work on enzymes and the curious family *Podostemonaceae*. He founded, however, a school of plant physiology, which is now well-known throughout the world.

In the beginning, Went directed his attention mainly to microbiological and mycological problems. Later on, however, systematic research was directed along two lines—one of them inspired by F. F. Blackman's theory of limiting factors and the temperature-reaction velocity ratio in vital phenomena, and the other on the nature of plant movements, where Pfeffer's conceptions were fundamentally attacked. A number of papers were issued in course of time on the influence of the temperature and limiting factors on the rate of germination, growth, respiration, carbon assimilation, protoplasmic streaming and also on the perception and reaction to 'stimuli' by plants.

The name of Went, however, is most closely connected with the problem of plant movements and especially with that of tropisms and growth. The nature of the problem was formulated in Blaauw's thesis (1909). The dependence of the phototropic response on the *quantity* of light (Blaauw), analogous relations in geotropism (Mrs. Rutten-Pekelharing) and finally the correlation between quantity of light and the phototropic curvatures (Arisz, 1914), suggested an exact quantitative analysis of tropisms. These investigations received a fresh impetus from Blaauw's.

theory that phototropism represents a special case of photo-growth reactions (1913). The succeeding period was devoted to exact measurements of growth, especially in *Avena* coleoptiles, as influenced by illumination and gravity (1919–26). Although a large amount of data was collected, it did not help much in visualising an internal mechanism of growth and tropisms.

The whole aspect and technique of the problem were changed, however, by the isolation of the growth substance (auxin) by Went's elder son (F. W. Went, 1927), and by his successful attempts to elaborate a physiological method of quantitative analysis of this growth substance. A large number of papers was published in the succeeding years on the relation of auxin to phototropism and geotropism, its distribution and transport, its formation in the root and its influence on the plasticity of the cell wall. Further, the chemical nature of auxin was revealed by Kögl and his collaborators (Haagen Smit, Miss Erxleben), also at Utrecht in the University Chemical Laboratory.

It was not in biology alone that Went was a man of outstanding importance. A member of the Royal Academy of Sciences, Amsterdam, since 1898, he was elected president in 1921. In this capacity he succeeded Lorentz, who strove after the War to bring together again scientific men of different nations. Went followed the example of his great predecessor with the same idealism, and finally succeeded in getting international scientific relations re-established to a large extent. Went thus played an important part in international scientific congresses.

Went was at the height of his scientific importance and international fame when he died. He retired from the chair of botany in Utrecht in July, 1934, and took an active part, until his death, in the preparations for the International Botanical Congress, of which he was president-elect. On several occasions during his life, for the last time on the occasion of his seventieth birthday, appreciation of his work was shown: in 1930 he was given the honorary degree of doctor of science of the University of Cambridge; in 1931 he was elected a foreign member of the Linnean Society of London, and in 1933 of the Royal Society. In Went we have lost a man of great qualities: his death will be deplored far beyond the boundaries of his own country.

Miss Nina F. Layard

WE regret to record the death of Nina Frances Layard, archæologist, which took place after an operation at the age of eighty-two years. She was a daughter of the Rev. C. C. Layard, rector of Combe Hay, Bath, and a niece of Sir Austen Layard, the excavator of Nineveh.

Miss Layard was not only the first woman to be elected a fellow of the Society of Antiquaries, but she was also one of the first of those women who took up seriously and earned distinction in the scientific study of archæology in the field. She was for long one of the most prominent of the students of East Anglian archæology, especially in the neighbourhood of Ipswich, holding that position almost as much by her success in stimulating the enthusiasm of others as by her own researches. These, however, especially in her studies of the industries of the palæolithic period, brought her no small reputation outside local circles, and on more than one occasion her work received the public commendation of Sir John Evans.

In addition to her finds of the palæolithic period, of which she submitted accounts to the British Association or published in the *Journal of the Royal Anthropological Institute* and other archæological publications, Miss Layard made an interesting and unusual discovery of what she held to be a prehistoric communal kitchen and a neolithic mining area, and superintended the excavation of an Anglo-Saxon cemetery, the relics from which are to be found in the Ipswich Museum. She also did much work on the investigation of remains of the Roman and medieval periods. In addition to her contributions to the *Journal of the Royal Anthropological Institute*, the *Proceedings of the Prehistoric Society of East Anglia* and other publications, Miss Layard was the author of a history of Ipswich School, of "Seventeen Suffolk Martyrs", and of two volumes of verse.

Dr. C. F. Marbut

SOIL investigators all over the world will learn with deep regret of the death of Dr. C. F. Marbut at Harbin. Early in August, he had attended the International Congress of Soil Science at Oxford, and had presided over the Section of Soil Classification and Mapping. He did not accompany the members on their excursion around Great Britain, but left instead for China, where he was to spend a year studying the soils and advising generally in regard to their mapping. Afterwards he was to go to Rome to work at the International Institute of Agriculture on the preparation of a map of the world's soils. But he was struck down by pneumonia on his voyage and died at Harbin.

Marbut began his career as a teacher in Nebraska, then became professor of geology in the Missouri University. He joined the Bureau of Chemistry and Soils of the United States Department of Agriculture at Washington and by 1912 he was appointed chief of the Division of Soil Survey: it was here that his best work was done.

Up to the time that Marbut took charge, the American soil surveys had been mainly based on the mechanical analyses of the surface soils. Marbut was essentially a field man, and discarded this analytical basis for a study of the characteristics of the soil as revealed by direct examination of the profile. This was, of course, accompanied by chemical and mechanical examinations, but the perspective was different: the interest lay in the morphology of the soil rather than in the units out of which it was made. This was in accordance with the developments of the subject being made in Russia by Glinka and others, the importance of which he recognised by translating into English the German edition

of Glinka's classical work "The Great Soil Groups of the World".

A little later Marbut had the opportunity of testing the new ideas by constructing a soil map of Africa. The actual task of making vegetation observations and collecting soil samples was carried out by Dr. Schantz in a rapid journey round the continent: the samples were very few, yet so firm was Marbut's faith in the new generalisations that he did not hesitate to construct the map, which was published in 1923 in "The Vegetation and Soils of Africa" and still serves a useful purpose.

In 1927 Marbut was in charge of the party of soil workers who travelled round the United States after the First International Soil Congress at Washington, and won great respect from his colleagues for his wide knowledge of American soils. He also visited Russia in 1930 for the second Congress, and studied the great soil groups of that country.

Marbut's great work was the organisation of the United States' soil survey, the first to be completed on modern lines. To the credit of the Department, his services were retained after he had passed the retiring age so that he might remain in charge to the end. The map was completed a few months ago.

Marbut was not merely a shrewd observer, but also a man of great personal charm, and had a singular power of capturing the affections of his colleagues. Tall, spare of build, alert and very active, with finely moulded features, he was a striking figure in the various scientific conferences he attended, and he never failed to attract and hold the attention of his audiences. His work will long survive to influence the activities of his successors.

News and Views

Norfolk Woodhenge

As stated in the preliminary announcement of the arrangements for the Norwich meeting of the British Association this year, the Norwich Research Committee has undertaken the excavation of the remarkable example of the type of monument, known to archæologists as 'Woodhenge', in the parish of Arminghall in the south-eastern outskirts of the city. The generic term 'Woodhenge' was first used by Mrs. M. E. Cunnington to describe the circle near Amesbury with wooden uprights in place of stone, which she excavated in 1926 and 1928. The Norfolk Woodhenge, which was discovered from the air in 1929, was known from air photographs to be a striking example of the type, consisting of two concentric rings, in the inner and broader of which was a gap giving access to the central space, around which were nine dark patches, presumed to be the post holes of the uprights of the circle. The completion of the work of excavation, which has been carried out under the direction of Mr. J. G. D. Clark, will enable members of the British Association, who have not previously had the opportunity, to form an idea at first hand of this striking development in the history of prehistoric monuments. In a preliminary report of the results of the excavation communicated to *The Times* of September 3, it is stated that excavation has confirmed the surface indications of a diameter for the outer circle of 262 ft. and for the central area within the smaller circle of 87 ft. The outer circle was found to be a ditch 12 ft. wide and 4 ft. 8 in. deep, the inner circle a ditch 28 ft. wide and 7 ft. 8 in. deep. As anticipated, the dark patches of the photographs are post-holes with ramps. The posts were found to consist of oak trunks some 3 ft. in diameter, set to a depth of 7 ft., after charring for preservation. It was evident that they had been dragged into position before the construction of the great inner ditch. No trace of burial was found in the enclosure, though there is evidence of burials nearby. Pottery of the Beaker type dates the structure at 1800–1500 B.C.

Cotswold Long Barrow

EXCAVATION of a long barrow near Notgrove in the Cotswolds has revealed an interior structure of a remarkable and, in certain respects, unusual character. The barrow is situated on a side road off the Cheltenham – Stow-on-the-Wold road, near the Notgrove G.W.R. station. It is being excavated by Mrs. E. M. Clifford with the assistance of a party of Cambridge students. The chamber, according to a report of the excavation which appears in *The Times* of September 2, is of the double cruciform type, which is rare in England, only about half a dozen examples being known. It has a horned entrance in dry stone walling —that is, the sides are prolonged to enclose partially a space at the entrance—and on the north side is a revetment wall in an excellent state of preservation. The south side, and also part of the north side, have been found to be enclosed by a rampart built of stone. The extent of this structure is being traced by further excavation. The most unusual feature, however, is a 'rotunda', a circular structure of large stones surrounded by a dry wall at the west end of the chambers—a form of structure of the greatest rarity, of which the purpose is unknown. These unusual features, which tempt comparisons that would be hazardous without plans and photographs, press for early publication of full details.

Celsius, Linnæus and the Centigrade Thermometer

THE history of the centigrade thermometer is discussed by Dr. N. V. Nordenmark (*Svenska Linné-Sällskap. Årsskrift*, **18**, 124; 1935). He points out that the thermometer of Anders Celsius used the scale of de l'Isle, the freezing point being at 100°,

the boiling point at 0°. Celsius's diaries are preserved at the Observatory of Uppsala, and show the development of his experiments with thermometers. The centigrade scale with freezing point at zero and boiling point at 100° appeared in 1747 on a thermometer bearing the name of its maker, the optician Ekström. It was constructed by Linnæus. In 1745, Linnæus had demonstrated to the Senate of the University his new thermometer, which in a letter to Sauvage he describes: "Ego primus fui, qui parare constitui thermometra nostra, ubi functum congelationis 0 et gradus coquentis aquae 100". It is strange that this centigrade thermometer of Linnæus, soon in universal use, and known at first as "the Swedish thermometer", should ever have become associated with the name of Celsius. But perhaps it was a casual association suggested by the C. for centigrade, together with the fact that Celsius was known to have experimented with thermometers.

Public Relations Work

In a pamphlet entitled "Whither Public Relations Work?" Dr. William A. Hamor, of the Mellon Institute of Industrial Research, Pittsburgh, emphasises the need of accumulations of facts about the social structure upon which public relations work rests, in order that the principles evolved will not crumble through faulty foundation work and therefore discourage this highly important managemental aid of the future. The development of such a science as sociology, especially for application in the province of public relations, requires investigators who are willing to achieve a thoroughly disinterested point of view toward the whole life of society for the purposes of their work. It is to be hoped that the day will soon come when an organisation may be established in which far-sighted social science research of a type corresponding in importance to physical science investigation may be carried forward extensively with the co-operation of management. When sociology has reached that plane of development, much of the guess-work that is now necessary—much of that costly element of chance—will gradually be eliminated from management as a whole as well as from the direction of public relations activities.

Re-awakening of Geysir at Hawkdale, Iceland

After a sleep of nineteen years, Geysir, the hot spring in Iceland from the name of which the term 'geyser' was derived, has been awakened to renewed activity by three research workers, Trausti Einarsson, Jón Jónsson of Lang (Bath) and Gudmundur Gislason. The report of the revival of Geysir appeared in the *Morgunblad* of July 30, announcing the fact that magnificent jets were thrown up 40–50 metres high. Later, however, comes another account stating that Geysir spouted fifteen times on that day, that as of old the highest jets were delivered in the morning and about eleven o'clock at night. Eruptions are very sudden, preceded by bursts of steam, and, as it is dangerous to be near, sketches of these are more or less guess-work. Following the steam, water 'cascades' all around the crater, and the accompanying steam renders photographs or measurements useless. None of the jets has actually been measured. It was Dr. T. Einarsson who conceived the idea of awakening Geysir. He realised that the 'saucer' of the geysir was the most important factor concerned, providing a large surface of water from which heat was radiated as fast as it was supplied from below, thus preventing the accumulation of heat in the pipe below necessary to produce the outburst. Consequently a gap was made in the lip of the saucer to prevent the water spreading out. The experiment was justified, and Geysir continues its old activity The road from Parliament Fields to Geysir, 118 kilometres in length, is to be improved, so that motor-cars may be able to undertake the journey.

Speed and Engineering

In his presidential address to the Sheffield section of the Junior Institution of Engineers, Mr. Allan J Grant gave an interesting account of the development of speed in engineering. Up to the advent of railways, about 1830, a speed of about 30 miles an hour was the maximum. By the use of steam trains a speed of 100 miles an hour was made safe. In 1933 the motor-car *Bluebird* did 272 miles per hour. The motor-boat *Miss Britain III* recently attained a speed of 111 miles per hour. To attain this speed, 1,375 horse-power had to be transmitted through a shaft only $1\frac{1}{8}$ in. in diameter. At the outbreak of the War, the most advanced aeroplane engines developed about 100 brake horse-power, and weighed about 4 lb. per horse-power, and the average speed varied from 60 miles to 90 miles per hour. The modern 'sprint' engines run at more than 3,000 rev. per min. and weigh only $\frac{2}{3}$ lb. per b.h.p. The recent flight of Charles Ulm to Australia in 6 days 18 hours proves the capabilities of small aircraft. Jules Verne's speed in "Round the World in 80 Days" is no longer fantastic. In fact, velocities would only have to be slightly more than doubled to become 1,000 miles an hour. At this speed, it would be possible for an airman starting at the equator at sunrise and flying west to arrive in 24 hours at sunrise and have continuous sunrise all the way round. If he flew in the latitude of London he would only have to fly at 620 m.p.h. to obtain the same effect. At the present time, it would not be possible for him to carry sufficient fuel for the purpose.

Railway Electrification

In an address broadcast from Radio Paris on May 16 and published in *Le Genie Civil* for June 22, Prof. H. Parodi says that the problem of railway electrification has come to the forefront in all the countries of the world. Between 1927 and 1933 more than 6,800 miles were electrified throughout the world, more than 3,000 being in Europe. The electrification of the Paris–Orleans, Orleans–Tours and Vierzon–Brive railway is an excellent example of main-line electrification, as all the services, signals, illumination, etc., are carried out electrically. Every discovery in the realm of power-production accelerates

the spread of electrification. In electric power stations, lignite, oil, coke-oven and blast furnace gas are used as well as coal and water-power. In France, electrification is from certain points of view imperative as France has to purchase coal and oil from abroad whilst it possesses great internal water-power resources. The consumption of fuel by French railways amounts to 42 million tons, of which 30 millions has to be imported. At the present time, France utilises 8,000 million kilowatt hours of energy generated by water-power or about 20 per cent of its maximum potential water-power resources. In Italy the policy of exploiting the natural wealth of the country has been systematically pursued. More than 1,200 miles of Italian railways are electrified and 3,000 miles are in progress. Similar, but less far-reaching programmes, have been prepared and are being carried out in Switzerland, Sweden and Bavaria. The electrical machinery employed is almost entirely automatic and entails operation, maintenance and repair charges considerably lower than steam locomotives.

Centenary of the Great Western Railway

ON August 31, 1835, after an unduly protracted and very expensive Parliamentary struggle, the Royal Assent was given to the Bill authorising the construction of the railway between Bristol and London, to which two years earlier the name of the Great Western Railway had been given. Notable among British railways for many reasons, the Great Western Railway as it is to-day has a fine record of achievement, and last week the centenary of the passing of the Bill which brought it into being was commemorated in various ways. On the evening of August 30, the B.B.C. included in its programme an account of the railway and its many activities, while on August 31, *The Times* issued a Great Western Railway Centenary Number as a special supplement, of 28 full-sized pages. The forty articles in this supplement include not only sketches of the history of the line, a biography of Brunel and a review of locomotives and rolling stock, but also others dealing with co-operation in transport, speed, safety and comfort in travel and the organisation of a great railway. As is well known, when planning the Great Western line, Brunel adopted the 7 ft. or broad gauge, as compared with the 4 ft. 8½ in. or narrow gauge, as used by the Stephensons and others, and it was this that gave rise to the famous "battle of the gauges". When that battle was at its height, a Royal Commission reported that the broad gauge was superior for speed and steady running, and for the greater capacity of the engines, but as there were then 1900 miles of narrow gauge line in existence as compared with only 274 miles of broad gauge, the verdict was given in favour of the former. This and other matters are all dealt with in an interesting manner in *The Times* supplement, which will remain of permanent value to all students of transport.

International Commission of Agriculture

THE International Commission of Agriculture (International Union of Agricultural Associations) recently held its general assembly at Brussels and Gembloux (Belgium) under the chairmanship of the Marquis de Vogüé (France), president. Among the problems discussed were the organisation of agricultural production under planned economy, edible fats, limitation of pig breeding and fattening (with special reference to attempts made in Denmark and Holland). The assembly devoted special attention to the present condition of agriculture. It came to the conclusion that in spite of the fact that useful measures have been taken in several countries since 1932, conditions of agriculture have grown worse. The Commission is convinced that the two main problems to be solved in order to overcome the agricultural crisis are the wheat problem and the edible fats problem: on one hand the London Wheat Agreement (1933) should be prolonged and improved; on the other, the older civilised countries should take measures or improve the existing measures in order to prevent consumption of tropical fats and whale oil, which handicaps the normal production and consumption of butter and lard. The Commission will hold its next meeting in 1936, in Oslo. It has been decided that the twelfth International Congress of Agriculture shall take place at The Hague in 1937.

Religious Motives in Medical Biology

IN the April issue of the *Bulletin of the Institute of the History of Medicine* Dr. Walter Pagel deals successively with the doctrines of Paracelsus, Hieronymus Hirnhaim, the alchemists of the seventeenth century and their adversaries, Marcus Marci, Robert Fludd, Mersenne and Robert Boyle, to illustrate the presence of religious motives in the medical biology of the seventeenth century. Dr. Pagel first shows that to Paracelsus and his religious view is due the modern conception of disease in the establishment of three new doctrines, namely: (1) the external cause is the essence of disease; (2) the organ involved and the anatomical changes decide the nature of the disease; and (3) disease consists of a complicated disturbance of organ metabolism which secondarily reflects upon the whole system. Hirnhaim, who regarded sympathy and antipathy as fundamental phenomena, adopted a pious scepticism which was the philosophical basis of idealistic biology and pathology. On the other hand, the pious conceptions of Nature and magic in the writings of the seventeenth century alchemists led to their embarking on a course of independent empirical research, their point of view being partly due to a positive appreciation of magic as a systematic imitation of Nature by means of arbitrary variation of the conditions of natural processes. After discussing the speculative embryology of Marcus Marci and his application of the physics of light to the explanation of life according to the principles of optics, Dr. Pagel gives an account of the "Medicina Catholica" of Robert Fludd, and shows at once the similarity of his conceptions with, and the fundamental differences from, the Romantic natural philosophy during the early nineteenth century. In conclusion, consideration is given to Robert Boyle and his theory of corpuscles as a scientific explanation of the mystery of specificity, forms and final causes.

Polish Science in the Middle Ages

THE principal contribution to vol. 20 (1935) of the annual publication, *Nauka Polska* (Polish Science), is a lengthy memoir, complete with index, by Prof. Stanisław Kot entitled "Anglo-Polonica". In it the author traces the contact between Polish men of culture and their fellow workers in Great Britain. It appears that from the Middle Ages onwards quite a number of Polish theologians and some men of science and arts visited London, Oxford and Cambridge, and some made protracted stays. It was natural that educated Protestant Poles should look to England for guidance in the troublous Middle Ages for, like Britain, Poland was an asylum for the persecuted. Thus Komenský (Comenius) and other Bohemian brethren settled at Leszno. These settlers are included in the article as Polish men of science. Polish alchemists, including the famous Sedziwój (Sendivogius), met their English confrères and exchanged books and possibly recipes with one another, and also engaged in polemics. The section on alchemy is probably the most purely scientific part of Prof. Kot's article. No fresh evidence is brought to light, however, to show that the Polish alchemists were any less of charlatans than those of other countries. One point does, however, emerge, and it is that the Polish language was very widely used in Medieval Europe along the Baltic coast and in other places where it has since been displaced by German. No less than eleven important English works on science are among the twenty books reviewed in this issue of *Nauka Polska*, which can almost be considered as an Anglo-Polish number.

International Federation of Eugenic Organizations

THE report of the eleventh assembly of the International Federation of Eugenic Organizations, held in Zurich, in July 1934, under the presidency of Prof. E. Rüdin, has just been issued as a pamphlet of eighty-four pages and contains a full account of the proceedings in English and German. Prof. R. J. A. Berry opened a discussion on the diagnosis and grading of oligophrenia, to which Dr. H. O. Wildenskov of Denmark, Dr. G. Rudolf, Dr. Lothar Loeffler (Kiel) and others made contributions. Dr. Mjöen (Oslo) demonstrated his methods of testing musical ability, Prof. C. Spearman discussed the psychological basis of personality and Dr. M. Steggerda (Cold Spring Harbor) gave an account of his methods of racial psychometry in Yucatan. Dr. F. von Verschuer (Berlin) described his methods of distinguishing monozygotic from dizygotic twins, with some new facts on tuberculosis in twins. Other contributions were made on the inheritance of various ocular abnormalities, by Dr. P. J. Waardenburg, and several pedigrees of chorea were explained by Dr. G. P. Frets. Dr. Ruttke and Dr. Astel gave an account of the working of the sterilisation law in Germany. Reports of progress in eugenics were received from representatives of Norway, Denmark, Holland, Poland, Austria, Czechoslovakia and the Dutch East Indies. The proposals of the Human Heredity Committee to establish in London a Central Bureau for Human Genetics, with affiliated bureaux in various countries, are given at length, the funds required for this purpose being about £2,000 annually for four or five years. Copies of this report can be obtained, price 3*s*. 6*d*., from the Hon. Secretary, Mrs. C. B. S. Hodson, 443 Fulham Road, London, S.W.10.

American Collecting Expeditions

DURING 1935 the Academy of Natural Sciences of Philadelphia, founded in 1812, the oldest institution of its kind in America, has sponsored twenty-four expeditions for collecting and field work in thirteen foreign countries and various parts of the United States. The most thrilling of these are perhaps the African expedition headed by George Vanderbilt, which has secured gorillas and okapis for new habitat groups and large collections of other mammals, birds, reptiles, fishes and insects; Brooke Dolan's expedition to western China and eastern Tibet; R. M. de Schauensee's collection of birds, fishes and orchids from the central highlands of Guatemala, and aquatic life from Lake Atitlan, 5,000 feet above sea-level. In Siam this collector-naturalist, after his third expedition there, organised a permanent field staff with headquarters in Bangkok which continues to gather much interesting material; and in Siberia Dr. E. B. Howard is searching for fossil remains of man which would link up with the earliest human arrivals on the American Continent. In America, expeditions are at work on the high plateau of Central Mexico, in the mountains of Panama, Cuba and the West Indies, Alaska, Wyoming, Bolivia, New Mexico and Louisiana.

The Strangeways Laboratory

IN their report for 1934, the trustees direct attention to the amount of work carried out at the Strangeways Research Laboratory, Cambridge, at very small expense, and appeal for further support. The increase in subscriptions and endowment has not kept pace with the increase in the work and the growing demand for funds to finance new work. The appeal is not for an extravagant scheme of expansion, since one of the advantages of the laboratory is that it is housed in a small building where the staff can work as a team with constant opportunities for discussion and co-operation, but for a sufficient income to enable the director, Dr. Honor Fell, and her colleagues to carry out their work this year with the apparatus and materials they need, and to plan next year's work with confidence that the funds required will be available. The trustees cannot count as a permanent source of income the grants from the Royal Society and Medical Research Council which have been provided for several years. As regards research work, steady progress has been made in fields which lie within the overlapping borders of general biology and medicine. The cultivation of living embryonic tissues in artificial media helps to reveal the factors which control normal growth, both of the individual cells and of the different tissues in relation to each

Supplement to "NATURE"

No. 3436 SATURDAY, SEPTEMBER 7, 1935 Vol. 136

Form, Drift, and Rhythm of the Continents*

By Prof. W. W. Watts, F.R.S.

President of the British Association

IT is now sixty-seven years since the British Association enjoyed the hospitality of the city of Norwich, a privilege which is being renewed under the most happy auspices.

At that meeting we find the scientific community was particularly interested in underground temperatures and tidal phenomena, in the application of the spectroscope to celestial objects, and in the discovery of the oldest Cambrian fossils and the earliest fossil mammals then known. Many papers were read on local natural history, including those on Norfolk farming and the drainage of the county and of the Fens.

In his address at the meeting the president, Sir Joseph D. Hooker, made special reference to the work of Charles Darwin: not to the "Origin of Species" which had been acrimoniously discussed by the Association on previous occasions, and notably at Oxford in 1860, but to some of the work that followed.

It should be remembered that Hooker was one of the three scientific men, representing botany, zoology and geology, whom Darwin had selected as judges with whose opinion on the soundness of his theory of the origin of species he would be content. The others were Huxley and Lyell; and of the three Lyell was the hardest to convince, chiefly because the record of life in the past then furnished by the rocks was manifestly so incomplete and unsatisfactory that its evidence was insufficient to warrant a definite verdict.

Uniformitarianism

Lyell had set out to "treat of such features of the economy of existing nature, animate and inanimate, as are illustrative of geology", and to make "an investigation of the permanent effects of causes now in action which may serve as records to after ages of the present condition of the earth and its inhabitants". By laborious study of the work of others, and by his own extensive travel and research, he had been able to enunciate, for the inorganic world, the principle of uniformitarianism, which in its original form we owe to Hutton. This principle involved that the history revealed by the rocks should be read as the effect of the slow but continuous operation of causes, most of them small, such as could be seen in action in some part or other of the world to-day. This was set in opposition to the opinion of the older geologists, who had postulated a succession of catastrophes which, by flood, fire and convulsion, had periodically wrecked the world and destroyed its inhabitants; each catastrophe necessitating a new creation to provide the succession of life on the earth as it then was known.

But in the organic world, Lyell, like Hutton, had failed to detect any analogous principle, and, as he rejected all the theories of transmutation of species then in vogue, he had to accept their absolute fixity; and to suppose that, as species became extinct one after another, replacement by special creations followed. Yet the reading to-day of the chapters devoted to this branch in the earlier editions of Lyell's great work produces the haunting feeling that a better explanation had only just eluded him. It was the story revealed in Lyell's work, Darwin tells us, the new conception that the earth had been in existence for vast æons of time, the proof that it had been continuously peopled by animals and plants, and that these had steadfastly advanced and improved throughout that time, which showed him the necessity for an explanation of the progression of life, and gave him the first hints of his theory.

* Presidential Address delivered at Norwich on September 4, 1935.

When he had enunciated this, he was enabled to repay his master with the principle of organic evolution, which brought changes in the animate world into harmony with those of the inanimate.

His "Antiquity of Man" shows that by 1863 Lyell had become a convert, and he afterwards rewrote much of the second volume of his "Principles" accepting the new point of view. This change earned from Hooker a testimonial in the 1868 address which, if not unique, must certainly be one of the most magnificent ever awarded to a scientific work:

"I know no brighter example of heroism, of its kind, than this, of an author thus abandoning, late in life, a theory which he had regarded as one of the foundation stones of a work that had given him the highest position attainable amongst contemporary scientific writers. Well may he be proud of a superstructure, raised on the foundation of an insecure doctrine, when he finds that he can underpin it and substitute a new foundation: and, after all is finished, survey his edifice, not only more secure, but more harmonious in proportions than before."

Although infinitely richer than when Darwin wrote, the geological record still is, and must from its very nature remain, imperfect. Every major group of animal life but the vertebrates is represented in the Cambrian fauna, and the scant relics that have been recovered from earlier rocks give very little idea of what had gone before, and no evidence whatever as to the beginnings of life. But, from Cambrian time onward the chain of life is continuous and unbroken. Type after type has arisen, flourished, and attained dominion. Some of them have met extinction in the heyday of their development; others have slowly dwindled away; others, again, have not finished their downhill journey, or are still advancing to their climax.

Study of the succession of rocks and the organisms contained in them, in every case in which evidence is sufficiently abundant and particularly among the vertebrates and in the later stages of geological history, has now revealed that the great majority of species show close affinities with those which preceded and with those which followed them; that, indeed, they have been derived from their predecessors and gave origin to their successors. We may now fairly claim that palæontology has lifted the theory of evolution of organisms from the limbo of hypothesis into a fact completely demonstrated by the integral chain of life which links the animals and plants of to-day with the earliest of their forerunners of the most remote past.

Further, the rocks themselves yield proof of the geographical changes undergone by the earth during its physical history; and indicate with perfect clearness that these changes have been so closely attendant on variation in life, and the incoming of new species, that it is impossible to deny a relation of cause and effect.

Indeed, when we realise the delicate adjustment of all life to the four elements of the ancients which environ it, air, water, earth and fire; to their composition, interrelationships and circulation; it is perhaps one of the most remarkable facts established by geology that, in spite of the physical changes which we know to have occurred, the chain of life has never snapped in all the hundreds of millions of years through which its history has been traced.

Rhythm of Sea and Land

The physical changes with which Lyell and his successors were most closely concerned were, first, the formation of stratified rocks on horizontal sea-floors, situated in what is now often the interior of continents, far removed from the oceans of the present day, and thus indicating important and repeated changes in the position of land and water; and, secondly, the deformation of these flat deposits until they were rucked and ridged to build the mountain ranges.

Before and since Lyell's time, geologists have devoted themselves to working out the exact and detailed succession of these stratified rocks, translating their sequence into history and their characters into terms of geography; the succession of physical conditions prevailing at the time of their formation. Further, although animals and plants migrate from place to place, the time occupied by the migrations of suitable forms is so negligible when compared with the length of the chapters of geological history that their fossil remains have proved to be the best means for correlating strata over broad stretches of the earth's surface. This correlation has converted the fragments of local history thus revealed into at least the outlines of the geological story of the world.

It was not until 1885, however, that the accumulation of data of this type was sufficient to enable the great geologist, Suess, an Austrian, but born in Great Britain, to assemble and correlate them, and to deduce from them further principles which have been the mainstay and inspiration of his successors. We owe to Hertha Sollas and her father the rendering of this great work, "The Face of the Earth", into English; and to Emmanuel de Margerie and his colleagues a French translation enriched with a magnificent series of maps and sections such as could only have been brought together by one with the most remarkable bibliographic knowledge: a veritable recension of the original.

The nature and associations and the distribution in time and space of modern changes in the relative levels of land and sea, as detected at sea-margins and by altitude survey, and of older changes betrayed by such evidence as submerged forests and raised beaches, had convinced geologists that the unstable element was not the fickle and mobile sea, but the solid if elastic earth-crust. They naturally applied the same explanation to those encroachments of the sea in the past which had resulted in the formation of our stratified rocks. But while some investigators were content with one form of movement—that due to lateral pressure—to explain both the formation of mountains and the rise and fall of the land, others called in a different cause for the latter. Without entering into a discussion of causes, it may be well for us to distinguish the orogenic or mountain-forming from the epeirogenic or continental movement.

The evidence collected by Suess proved that these last great land and sea changes had occurred simultaneously over whole continents or even wider regions. Such great submergences as those to which the Cambrian Rocks, the Oxford Clay, and the Chalk are due were of this character; while, in between, there came times of broad expansions of continental land and regressions of the sea. These changes were in his view on far too grand a scale to be compared with, or explained by, the trivial upheavals and depressions of land margins of the present day, which he showed could mostly be correlated with volcanoes or earthquakes, or with such incidents as the imposition or relief of ice-sheets on an elastic crust in connexion with glacial conditions.

It became necessary for him to replace or supplement oscillations of the earth-crust by a world-wide periodic ebb and flow of the oceans, to and from the continents; positive movements of transgression carrying the sea and its deposits over the lands, drowning them and their features under tens or hundreds of fathoms of water; and negative movements or regressions when the oceans retreated to the deeps, leaving the continents bare or encrusted with recently formed sediments.

Although the facts cried out for this generalisation, Suess was at a loss to supply any mechanism competent to produce the wonderful rhythm. The problem was difficult because a liquid must maintain a horizontal, that is, an equipotential, surface. It was manifestly impossible to withdraw from the earth, and later to replace upon it, the vast quantity of water that would be required; and, though a shifted water-level, or even a varied water-surface relative to the continents, might be caused by polar ice-caps, by redistribution of the continents carrying their local effects on gravitation, by variations in the rate of the earth's rotation, or other far-reaching causes, none of these would supply an explanation that fitted all the facts. Regressions of the sea could be to some extent explained if Suess's main postulate, that the great ocean basins had been slowly sinking throughout geological time, were granted. But this explanation only rendered more impotent the raising of ocean levels by deposits of sediment, and this was almost the only valid cause for transgressions that he had been able to suggest.

Further, it is not possible to ignore the definite relationship that exists between the pulsation of the oceans and the raising of mountains by lateral or tangential stress. Periods of positive movement or advance of the seas were times of comparative tranquillity, when tangential pressure was in abeyance. Periods of negative movement and retreat were invariably marked by the operation of great stresses by which the earth's face was ridged and wrinkled in the throes of mountain-birth.

Mountain Ranges

The theory that continuous cooling and shrinkage of the interior of the earth afforded an explanation of mountain ranges and other rugosities on its surface was a legacy from the nebular hypothesis. In spite of the homely simile of a shrivelling apple, this explanation has never received a very enthusiastic welcome from geologists, though, in default of other resources, they had to make use of it. As knowledge has grown, the difficulties have become insurmountable to them.

First, there is its inadequacy to explain the vast amount of lateral movement required to account for the greater mountain ranges; their rocks, originally spread over a wider area, having been folded and crushed into a narrower width. The shortening of the earth-crust thus effected has been estimated in the case of the Rocky Mountains at 29 miles, of the Himalayas at 62, the Alps at 76, and the Appalachians at the large figure of 200 miles.

Then there is the periodicity of mountain growth. The great epochs of mountain building, such as the Caledonian, to which the chief Scottish and Welsh mountains are due, the Hercynian, responsible for the Pennine and South Wales, and the Alpine, which gave us "the wooded, dim, blue goodness of the Weald", were associated with vast continental development; and each was separated from the next by a period of relative inactivity lasting dozens of millions of years.

Further, there is the fact that the vigour of mountain building, of volcanoes, and of other manifestations of unrest, has shown no sign of

senility or lack of energy. The geologically recent Alpine-Himalayan range is as great, as lofty, and as complicated in structure as were any of its precursors. The active volcanoes of Kilauea, Krakatao, or St. Pierre, and those recently extinct in northern Ireland and the Scottish Isles, were as violent and efficient as any of those of the Palæozoic era. The earth is 'a lady of a certain age', but she has contrived to preserve her youth and energy as well as her beauty.

Age of the Earth

It was when Lord Kelvin's dictum struck from geology its grandest conception, time, that it became vital to re-examine the position. He had demonstrated that, if the earth had been continuously cooling down at its present rate, its surface must have been too hot for the existence of life upon it a limited number of million years ago. The concept of geological time, indicated by Hutton in his famous saying that in this inquiry "we find no vestige of a beginning—no prospect of an end", had been confirmed by data accumulated through the painstaking researches of a host of competent and devoted observers all over the world. To them, familiar with the tremendous changes, organic and inorganic, that the earth had passed through since Cambrian time, it was wholly impossible to compress the life-story of the earth, or the history of life upon it, into a paltry twenty or thirty million years. The slow growth and slow decay of mountain range after mountain range, each built out of, and in some cases upon, the ruins of its predecessor; the chain of slowly evolving organisms, vast in numbers and infinite in variety; told plainly of long æons of time. The duration of these æons can be dimly realised when it is recalled that, within a small fraction of the latest of them, man, with the most primitive of implements and the most rudimentary culture, has succeeded in penetrating to the uttermost corners of the world, and developed his innumerable languages and civilisations.

Huxley took up the challenge in his address to the Geological Society in 1869, and asked the pertinent question, "but is the earth nothing but a cooling mass 'like a hot water jar such as is used in carriages' or 'a globe of sandstone' ?" He was able to point out at least some agencies which might regenerate the earth's heat or delay its loss.

So it is only fitting that the great physicist, who imposed a narrow limit to geological time, should have prepared the way for those who have proved that the earth possesses in its radioactive substances a 'hidden reserve' capable of supplying a continuous recrudescence of the energy wasted by radiation, thus lengthening out the time required to complete its total loss. These later physicists have given us time without stint; and, though this time is the merest fraction of that envisaged by cosmogonists and astronomers, we are now so much richer than our original estimates that we are embarrassed by the wealth poured into our hands. So far from the last century's urge to 'hurry up our phenomena', we are almost at a loss for phenomena enough to fill up the time.

The far-sighted genius of Lord Rutherford and Lord Rayleigh first saw the bearing of the rate of disintegration of radioactive substances in the minerals of rocks on the age of the parts of the earth-crust built of them. The extension and supplementing of this work, by Joly, Holmes and others, has now enabled us to look to the disintegration of uranium, thorium and potassium, as the most promising of many methods that have been used in the endeavour to ascertain the age of those parts of the earth-crust that are accessible to observation. These methods also promise a means of dating the geological succession of Eras and Periods in terms of millions if not hundreds of thousands of years.

The Earth Pulse

The decline and early death to which Lord Kelvin's dictum had condemned the earth, according so little with the vigour displayed in its geological story, is now transformed into a history of prolonged though not perennial youth. It was for Joly, of whose work the extent, variety and fruitfulness are scarcely yet fully appreciated, to take the next step and see in the release of radioactive energy a mechanism which could drive the pulse that geologists had so long felt, and that Suess had so brilliantly diagnosed. As Darwin found the missing word for Lyell, so Joly in his theory of thermal cycles has indicated the direction of search for a mechanism to actuate the rhythm of Suess.

In Joly's conception, the running down of the earth's energy, though a continuous process, was, through the intervention of radioactivity, converted into a series of cycles, during each of which relative movements of sea and land must occur; downward movements of the continents, associated with positive encroachments of the sea; upward movements, with retreat of the sea, the formation of wide land masses, and the ridging of strata to form mountain ranges. Thus he forged a link that could unite the continental or epeirogenic movement with orogenic or mountain movement.

The visible parts of mountains and continents, as well as their lower and hidden portions, or 'roots', are made of comparatively light rocks. In order to stand up as they do, their roots must be

embedded in denser matter, in which they 'float' like icebergs in water. A far larger mass must exist below than is visible above, and the bigger the upstanding part the bigger the submerged root. Over the larger area of the ocean floor, on the other hand, the thickness of material of low density must be very slight, and the denser layer must come close to the surface.

Thermal Cycles

The study of earthquakes, to which the Seismology Committee of the British Association has made outstanding contributions, has yielded, from the times taken in transmission of vibrations through the earth, the best information as to the nature and state of the interior. It has proved that the dense layer is solid at the present time. It is probably no coincidence that the earth is also but just recovering from what is possibly the greatest period of mountain building, if not the greatest negative movement of ocean retreat, that it has ever experienced.

But solidity cannot be the permanent condition of the substratum. Heat is generated in it by its own radioactivity, but, according to the terms of the hypothesis, cannot escape, in consequence of the higher temperature generated in the continental rocks which cover it. It is therefore retained in the substratum and stored as latent heat of liquefaction, so that, within a period which has been calculated approximately in millions of years, complete melting of the sub-crust must ensue.

The resulting expansion of the liquefied stratum will have at least two effects of great importance to us. In the first place, the unexpanded superficial layers will be too small to fit the swelling interior. They will, therefore, suffer tension, greater on the ocean floor than on land, and cracking and rifting will occur, with intrusion and extrusion of molten rock. In the second place the continental masses, now truly floating in a substratum which has become fluid and less dense than before, will sink deeper into it, suffering displacement along the rift cracks or other planes of dislocation. As a result the ocean waters, unchanged in volume, must encroach on the edges of the continents, and spread farther and farther over their surfaces.

Thus we have the mechanism which Suess vainly sought, causing positive movements of the oceans, their waters spreading over wide stretches of what was formerly continental land, and laying down as sediment upon it the marine stratified rocks which are our chief witness of the rhythmic advances of the sea.

This condition, however, cannot be permanent, for by convection of the fluid basic substratum, supplemented by the influence of tides within it, and the slow westward tidal drag of the continental masses towards and over what had been ocean floor, there will now be dissipation of its heat, mainly into the ocean waters, at a rate much faster than it has been or could be accumulated. Resolidification ensues, and again there are two main consequences. First, the stratum embedding their roots having now become more dense, the continental masses rise, and as they do so the ocean waters retreat from their margins and epicontinental seas, leaving bare as new land, made of the recently deposited sediments, the areas previously drowned. Secondly, the expanded crust, left insufficiently supported by the withdrawal of shrunken substratum, will suffer from severe tangential stress, and, on yielding, will wrinkle like the skin of a withering apple. The wrinkles will be mountain ranges, formed along lines of weakness such as those at continental margins; and they will be piled up and elevated, to suffer from the intense erosion due to water action upon their exposed and upraised rocks.

In this, again, we have a mechanism which supplies what was needed by Suess, and one, moreover, which secures the required relationship between continental and mountain movement, between the broader extensions of continental land and the growth of mountains with their volcanoes and earthquakes and the other concomitants of lateral thrust.

Thus a thermal cycle may run its full course from the solid substratum, through a period of liquefaction accompanied by crustal tension, back to solidification and an era of lateral stress: and the stage is set for a new cycle.

Prof. Arthur Holmes, in checking Joly's calculations, has concluded that the length of the cycles in a basic rock substratum should occupy 25–40 million years, a period much too short to fit the major periods of mountain movement, as determined by him from the radioactivity of minerals contained in the rocks. On this evidence the Alpine movement should date back 20–60 millions of years ago, the Hercynian 200–250 millions, and the Caledonian 350–375 million years.

In a preliminary attempt to modify Joly's hypothesis, Holmes postulated the occurrence of similar, but longer cycles (magmatic cycles) in a denser, ultra-basic layer underlying the basic one, the rhythm of which would be nearer to 150 million years. The shorter cycles due to the basic layer are held in part responsible for periods of minor disturbance, and also to account for the individual variations in effect, duration and intensity of the larger ones. Each of the later movements has also evidently been limited and conditioned by the results of foregoing ones, and especially by areas of

fracture and weakness on one hand, and by large stable masses composed of rocks intensely consolidated, or already closely packed, on the other.

More recently, Holmes has developed the possibility that the loss of heat is mainly due to convection in the liquid substrata, and that convection is the leading cause of the drifting and other movements of the crust, and the disturbances that have occurred in it. He says:

"Although the hypothesis involving sub-crustal convection currents cannot be regarded as established, it is encouraging to find that it is consistent with a wide range of geological and geophysical data. Moreover, it is by no means independent of the best features of the other hypotheses. It requires the local operation of thermal cycles within the crust, and it necessarily involves contraction in regions where crustal cooling takes place. It is sufficiently complex to match the astonishing complexities of geological history, and sufficiently startling to stimulate research in many directions".

The phenomena are difficult to disentangle as the number of operating causes has been so great and many of them are not fully understood. But, underlying them all there is unquestionably the pulse within pulse which Suess saw, and of which Joly pointed the way to explanation.

The view at which we have arrived is neither strictly uniformitarian nor strictly catastrophic, but takes the best from each hypothesis. As Lyell showed, most of the phenomena of geology can be matched somewhere and sometime on the earth of to-day; but it would appear that they have varied in place, intensity, phase and time. And, as Lyell was driven to accept *evolution* to explain the history of life on the earth, so must we employ the same word to express the life-processes of the earth itself, as was suggested by Huxley in 1869 and strongly advocated by Sollas in 1883.

The Atlantic and Pacific Oceans

The contrast in outline and structure between the Atlantic and Pacific Oceans had long been noted when Suess formulated and used the differences as the basis of his classification.

The Pacific is bounded everywhere by steep slopes, rising abruptly from profound ocean depths to lofty lands crowned with mountain ranges, parallel to its shores and surrounding its whole area. On the American side the coast range is continued by the Andes. On the Asiatic side chains of mountainous peninsulas and islands, separated from the continent by shallow inland seas, extend in festoons from Kamchatka and Japan to the East Indies, eastern Australia and New Zealand. This mountain ring, as Charles Lapworth said, "is ablaze with volcanoes and creeping with earthquakes", testifying that it has been recently formed and is still unfinished.

The Atlantic Ocean, on the other hand, is not bordered with continuous ranges, but breaks across them all: the Scottish and Welsh ranges, the Armorican range, the continuation of the Pyrenees and Atlas; and, on the American side, the uplands of Labrador, Newfoundland and the eastern States, and the hill ranges of Guiana and Brazil. The Atlantic is in disconformity with the grain of the land, while the Pacific conforms with it. The Pacific has the rock-folds of its ranges breaking like ocean waves towards it as though the land were being driven by pressure to advance upon it, while the Atlantic recalls the effects of fracture under tension.

The middle and southern edges of the Atlantic, however, agree to some extent with the Pacific type. The Caribbean Sea, with the Antilles and the rest of its border girdle, recalls the similar structure of the Mediterranean, as it stretches eastwards, with breaks, to the East Indian Archipelago; while the Andes are continued to Antarctica in a sweeping curve of islands. The rest of the Indian Ocean is of Atlantic type, as seen in the shores of eastern Africa and western Australia.

Continental Drift

Another feature of the Atlantic is the parallelism of much of its eastern and western coasts, the meaning of which has often attracted the speculations of geologists and geographers. With a little stretch of the imagination, and some ingenuity and elasticity of adjustment, plans or maps of the opposite sides may be fitted fairly closely, particularly if we plot and assemble the real edges of the continents, the steep slopes which divide the 'shelves' on which they stand from the ocean depths. This has suggested the possibility that the two sides may once have been united, and have since broken and drifted apart until they are now separated by the ocean.

This view, outlined by others, has been emphasised by Wegener and dealt with by him in full detail in his work on "The Origin of Continents and Oceans", and it now plays a leading part in what is known as the Wegener theory of continental drift. The hypothesis is supported by the close resemblances in the rocks and fossils of many ages in western Europe and Britain to those of eastern North America; by community of the structures by which these rocks are affected; and

by the strong likeness exhibited by the living animals and plants on the two sides, so that they can only be referred to a single biological and distributional unit, the Palæarctic region.

The hypothesis, however, did not stop at this; and in the South Atlantic and certain other areas Wegener and his followers have also given good reasons for believing that continental masses, once continuous, have drifted apart.

Broad areas in southern Africa are built of rocks known as the Karroo Formation, of which the lower part, of late Carboniferous age, is characterised especially by species of the strange fern-like fossil plants *Glossopteris* and *Gangamopteris*. Associated with them are peculiar groups of fossil shells and fossil amphibia and reptiles. Similar rocks, with similar associations and contents, in Peninsular India have been named the Gondwana Formation. Comparable formations also occupy large regions in Australia, Tasmania and New Zealand, in Madagascar, in the Falkland Islands and Brazil, and in Antarctica.

The correspondence between these areas is so close that Suess supposed they must at that date have been connected together by lands, now sunk beneath the sea, and he named the continent thus formed Gondwanaland after the Indian occurrences. The break-up of this land can be followed from a study of the rocks, and it was a slow process, its steps occupying much of Mesozoic time. Dr. A. L. du Toit's comparison of South African rocks with those of Brazil and elsewhere in South America favours even a closer union than this between the units now scattered.

One of the most remarkable features shown by these rocks in all the areas mentioned, but to varying extents, is the presence of conglomerates made of far-travelled boulders, scratched like those borne by the modern ice-sheets of Greenland and the Antarctic, associated with other deposits of a glacial nature, and often resting upon typical glaciated surfaces. There is no possible escape from the conclusion that these areas, now situated in or near the tropics, suffered an intense glaciation. This was not a case of mere alpine glaciers, for the land was of low relief and not far removed from sea-level, but of extensive ice-sheets on a far larger scale than the glaciation of the northern parts of the New and Old Worlds in the Pleistocene Ice Age. I have never seen any geological evidence more impressive or convincing than that displayed at Nooitgedacht, near Kimberley; while the illustrations and other evidence published by David and Howchin from Australia are equally striking.

Du Toit's work on these glacial deposits brings out two remarkable facts; first, that the movement of the ice was southerly, pole-ward and away from the equator, the opposite to what would be expected and to the direction of the Pleistocene ice-movement; secondly, that the ice in Natal invaded the land from what is now sea to the north-east.

When it is realised that at this period there is no evidence of glacial action in northern Europe or America, but a climate in which grew the vegetation that formed the coal seams of our Coal Measures, it is clear that we are not dealing with any general refrigeration of the globe, even if that would produce such widespread glaciation: we are face to face with a special glaciation of Gondwanaland.

On both sides of the Atlantic these glacial episodes in Carboniferous times were followed by dry and desert climates in Triassic time, and these by violent volcanic outbursts. Nor are the rocks alike only in mode of formation: the structures by which they are traversed correspond; while even in details there is remarkable agreement, as in the peculiar manganese deposits, and the occurrence of diamonds in 'pipes' of igneous rock, both east and west of the Ocean.

Rather than face the difficulties presented by the subsidence of lands connecting the severed portions of Gondwanaland, as pictured by Suess, Wegener has preferred—and in this he is supported by Du Toit and many other geologists—to bring into contact these severed parts, which could be fitted together as nearly as might be expected, considering the dates of severance. Du Toit's map of the period places South America to the west and south of South Africa, Madagascar and India to the east, Antarctica to the south, and Australia farther to the south-east. Such a grouping would form a continent much less wide in extent than that envisaged by Suess, and would offer some explanation of the more remarkable features of the glaciation in the several areas, as well as the problems of the rocks, fossils and structures involved.

In its application to the geology of Gondwanaland the modified hypothesis of Wegener cuts a Gordian knot; but it still leaves a great climatal difficulty, unless we take his further step and conceive that at this date the terrestrial south pole was situated within Gondwanaland. No shift in the axis on which the earth rotates would, of course, be possible, nor is it postulated: only a drifting at that date of continental land across the pole.

If a hypothesis of drift be admitted for Gondwanaland, it would be illogical to deny its application to other regions, including the north Atlantic. I have already mentioned some facts in its favour. Others are the resemblances of all sedimentary rocks on the two sides from the Cambrian to the

Ordovician, and from the Devonian to the Trias; the links between the structures of the land, as, for example, between Ireland and Newfoundland; and the instance given by Prof. E. B. Bailey in his address to Section C in 1928. As Bailey then pointed out, the great Caledonian range which crosses Scotland, northern England and Wales from north-east to south-west on its course from Scandinavia is affected and displaced by the east to west Armorican (Hercynian) chain extending across from Brittany to South Wales. "The crossing of the chains, begun in the British Isles, is completed in New England"; and from here the Armorican structure continues its westerly course. This is where it should cross if the continent of North America were brought back across the Atlantic and placed in the position which, according to Wegener, it would fit into in the European coast! Can the Pilgrim Fathers have ever dreamed of such a link between the Old England and the New?

The hypothesis of continental drift gave rich promise of solving so many difficult problems that it was hailed by many classes of investigators almost as a panacea. Geographers have seen in it an explanation of the forms of continents and the position of peninsulas, islands and mountains; meteorologists have found it the solution of some of the problems of past climates and their anomalies of distribution over the world; biologists hope to get help with the intense complexities in the distribution of forms of life and many strange facts in migration, and palæontologists with similar difficulties among the ancient faunas and floras as revealed by their fossil remains; geodesists have welcomed escape from the rising and sinking of the crust, so difficult to reconcile with the demands of isostatic equilibrium; and it has been already stated that drift forms a vital factor in Joly's thermal cycles.

But there has been no lack of criticism in all these directions. It has been assailed on one hand for the detail attempted in its geographical restorations, and on the other hand for its vagueness. Prof. Schuchert quotes Termier as saying that it is "a beautiful dream, the dream of a great poet. One tries to embrace it, and finds that he has in his arms but a little vapour or smoke: it is at the same time alluring and intangible". It has been objected that "no plausible explanation of the mechanics involved has been offered"; that the continental connexions postulated present by no means so close a match, when fitted together, as has been claimed, in the structure or the nature of either igneous or sedimentary rocks; that there is good evidence of extensive vertical movements in recent earthquakes, in the accumulation of tremendous thicknesses of sediment indicative of shallow-water from base to summit, and in the growth of coral reefs; that Central America and the Mediterranean are a difficult obstacle; and that the known distribution of the Karroo fossil reptiles is not by any means what the hypothesis demands.

If the idea of drift be accepted, it cannot be regarded as a royal road out of all our difficulties, nor can it be the only form of earth-movement to be reckoned with. The late J. W. Gregory, whose life was sacrificed to geological discovery, studied exhaustively the geological history of the Atlantic and Pacific Oceans, both as revealed by the sedimentary rocks and fossils on their borders, and by the distribution of life to-day. He found that, according to our present knowledge, in the two oceans, facilities for migration have fluctuated from time to time, periods of great community of organisms alternating with periods of diversity. Again, at some times connexion seems to have been established north of the equator, at others to the south; and we cannot ignore the possibility of migration across polar lands or seas when terrestrial climates have differed from the present. The facts of life distribution are far too complex to be explained by any single period of connexion followed by a definite breaking apart, even if that took place by stages. Mrs. Reid, too, has pointed out that resemblances between the Tertiary floras of America and Europe actually increased at the time when the Atlantic should have been widening. Unless continental drift has been a more complicated process than anyone has yet conceived, it seems impossible to escape from some form of the 'land bridges' of the older naturalists:

"Air-roads over islands lost—
Ages since 'neath Ocean lost—"

We have no right to expect greater simplicity in the life of a planet than in that of an organism.

As the question of drift must in the last appeal be one of fact, it is not unnaturally expected that the real answer will come from measurements of longitude and latitude with greater exactness and over periods longer than has yet been possible. None of the measurements hitherto made has indicated variations greater than the limits of errors of observation. Two things, however, may militate against a definite answer from this source. Many parts of the crust, such as the shield-like masses of Archæan rock, may have completed their movement, or be now moving so slowly that the movement cannot be measured. Careful selection of locality is essential, and at present we have little guidance. Also, as the displacement of crust must be dependent on the condition of its substratum, it will be a periodic phenomenon and the

rate of movement may vary much in time. According to the theory of thermal cycles the sub-crust is at present solid, and may not permit of drift. Drift, according to Joly and Holmes, is a cyclical phenomenon ; if present-day observations were to give a negative result they would not necessarily disprove it.

The occurrence of recumbent rock-folds, and nearly horizontal slides or 'nappes' in mountain regions, gives positive proof that parts of the upper earth-crust have moved over the lower. In the North-west Highlands of Scotland, a sliding of at least ten miles was proved by Peach and Horne, and in Scandinavia it amounts to sixty miles. For mountain packing as a whole the figures already given are far larger, while in Asia, Argand has stated that packing of more than 2,000 miles has occurred. Thus, when all is said and done, movements on a colossal scale are established facts, and the question of the future is how far we shall accept the scheme of drift due to Wegener, or one or other of the modifications of it. It is for us to watch and test all the data under our own observation, feeling sure that we shall have to adapt to our own case Galileo's words "e pur si muove".

Rock Folding and Mountain Birth

Ever since it was realised that the inclination and folding of rocks must be attributed to lateral or tangential stress and not solely to uplift, shrinkage of the interior of the earth from its crust has been accepted as the prime mover, and whichever of the current theories we adopt, we cannot deny the efficacy of so powerful a cause.

The general course of events in the formation of a mountain range is fairly well known : the slow sinking of a downfold in the crust during long ages ; the filling of this with sediment *pari passu* with the sinking, and associated softening of the sub-crust due to accumulated heat ; the oncoming of lateral pressure causing wave-like folds in the sediments and the base on which they rest ; the crushing of folds together until, like water waves, they bend over and break by over-driving from above or, it may be, under-driving from below ; fracture of the compressed folds and the travelling forward for great distances of slivers or 'nappes' of rock, generally of small relative thickness but of great length and breadth, and sliding upon floors of crushed rock ; the outpouring and intrusion of igneous rocks, lubricating contacts and complicating the loading of the sediments ; metamorphism of many of the rocks by crystallisation at elevated temperatures and under stress, with the development of a new and elaborate system of planes of re-orientation and movement ; and elevation of the whole, either independently or by thickening with compression and piling up to bring about a fresh equilibrium.

Such a course of events would be brought about by lateral pressure developed during the consolidation phase of each of the thermal or magmatic cycles. At each period of their building, mountains have arisen along lines of weakness in the crust, especially coast lines and the steep slopes marking the limits between continents and ocean basins. This is consistent with Joly's theory that the thrust of ocean beds against land margins is the cause.

The advocates of continental drift point to the siting of ranges across the paths along which the drifting movement is supposed to have occurred, and they consider that the moving masses are responsible ; and indeed that the ridging and packing of the crust has in the end checked and stopped the movement. They note that the great western ranges of America occur in the path of any western drift of that continent, the Himalayas in the course of the postulated movement of India, the East Indies in front of Australia ; and that the Alpine ranges of Europe may be linked with the crushing of Africa towards the north.

The 'nappes' of rock, cut off from their origin and sliding for dozens of miles, are a constant source of wonder to all who have considered the mechanics of mountain formation. They are so thin as compared with their great length and breadth, that it seems impossible to imagine them moved by any force other than one which would make itself felt throughout their every particle. Such a force is gravitation, and it is of interest that some Alpine geologists and Dr. Harold Jeffreys have used it in explanation of them. Prof. R. A. Daly has also adopted gravitation on an even greater scale in his theory of continental sliding : and one cannot fail to notice the increasing use of the term 'crust-creep' by those working on earth-movement.

Is there no other force, comparable in its method of action to gravitation, but capable of producing movement of the earth-crust in a direction other than downhill ? Is it not possible, for example, that the tidal influence of the moon and sun, which is producing so much distortion of the solid earth that the ocean tides are less than they would be otherwise, and, dragging always in one direction, is slowing down the earth's rotation, may exert permanent distorting influence on the solid earth itself ? May it not be that such a stress, if not sufficiently powerful to produce the greater displacements of continental drift and mountain building, may yet take advantage of structures of weakness produced by other causes, and itself contribute to the formation of nappes and to other movements of a nature at present unexplained ?

Geological Surveying

Our knowledge of geology has been gained by the survey of the rocks, the study of their structures, and the delineation of both upon maps and sections. This work is being accomplished by geologists all over the world, and Great Britain and the Empire have contributed their full share. It is therefore opportune to note that there has just been celebrated the centenary of the Geological Survey of Britain and, with it, the opening of the new Geological Museum at South Kensington.

A century ago H. T. de la Beche, one of the devoted band of pioneer workers then studying the geology of the country, offered to "affix geological colours to the new maps of Devon and Cornwall" then in course of issue by the Ordnance Survey. His offer was accepted, and, at his own expense and on his own feet, he carried out a geological survey of some 4,000 square miles. In 1835 he was appointed to continue this task, with a small salary and a few assistants. Thus was started the first official geological survey, an example widely followed by other nations and dominions. De la Beche's conception included also a Museum of economic and practical geology, a Library, a Record of Mines, for which he secured support from a strong committee of the British Association in 1838, and a School of Mines for the scientific and technical education of those to be employed in the survey or exploitation of mineral resources. In these objects, and especially the last, he was warmly supported by the Prince Consort. He lived to see his visions all come true, as he collected round himself that wonderful band of surveyors, investigators, writers and teachers, which included such men as Playfair, Logan, Ramsay, Aveline, Jukes, Forbes, Percy, Hooker, and Huxley.

Some of the schemes planned by de la Beche have budded off and grown into large and important entities, rendering conspicuous service to scientific record, education, and research. But the main duties of the Geological Survey remained with it, and have been carried on for a century. These are to map the geology of the country on the largest practicable scale, to describe and interpret the structure of the land, to preserve the evidence on which conclusions have been founded, and to illustrate for students and other workers the geology of the country and its applications to economics and industry. The broad detail of the structure of the whole country is now known, but much new work must be done to keep abreast of or to lead geological thought. For example, the study of the cloak of 'superficial deposits', which often cover and conceal the structure of the more solid rocks below, is essential for the proper understanding of soils and agriculture; and a knowledge of the deep-seated geology of the country, which is often widely different from that nearer the surface and thus very difficult to interpret, is vital to the community for the successful location and working of coal and iron, and for tracing supplies of water and oil and other resources at depth.

Evolution of Life

Evolution of life on the earth has been by no means uniform; there have been periods of waxing and waning which may be attributed to geographical, climatological, and biological influences. The development of large land areas, ranged longitudinally or latitudinally, the invasion of epicontinental seas, the isolation of mediterraneans or inland seas, the splitting of continental areas into archipelagos or the reunion of islands into continuous land, the making of barriers by the rearing of mountain chains or the formation of straits or arms of the sea, the oncoming of desert or glacial climates; all such factors and many others have been of importance in quickening or checking competition, and in accelerating or retarding the evolution of life.

Probably, however, even greater effects have followed the interaction of groups of biological changes on one another. As an example I might recall Starkie Gardner's estimate of the results following upon the first appearance of grasses in the world. This seems to have been not earlier than Eocene, and probably late Eocene times. By the Oligocene they had made good their hold, peculiarities in their growth and structure enabling them to compete with the other vegetation that then existed; and gradually they spread over huge areas of the earth's surface, formerly occupied by marsh, scrub and forest. They have, as Ruskin says, "a very little strength . . . and a few delicate long lines meeting at a point . . . made, as it seems, only to be trodden on to-day, and to-morrow to be cast into the oven"; but, through their easy growth, their disregard of trampling and grazing, and by reason of the nourishment concentrated in their seeds, they provided an ideal and plentiful source of food.

On the establishment of the grasses, we find that groups of animals, which had previously browsed on shrubs and trees, adopted them, with consequent alterations and adaptations in their teeth and other bodily structures. To follow their food from over-grazed or sun-scorched regions they required to be able to migrate easily and quickly, and it was essential for them to discard sedentary defence and to flee from threatened danger. Such defence as was possible with heels, teeth or horns they retained; but the dominant modifications in

their organisation were in the direction of speed as their vital need.

Side by side with this development, and in answer to increasing numbers, came bigger, stronger and speedier carnivores, to feed on prey now so much more abundant, but more difficult to catch. The answer of the grass-feeders, with their specialised hoofs, teeth and bones, better suited to flight than fight, was to seek safety in numbers, and thus develop the herd instinct, with its necessity for leadership and discipline; but this, in turn, provoked a like rejoinder from some types of their enemies.

When it is remembered how much of the meat and drink and life of mankind is bound up with the grasses, including wheat, maize, millet and other grains, sugar-cane, rice and bamboo, we must realise how close is his link with the development just outlined. Practically his whole food supply is provided by them, either directly by the agriculturist who grows little else but grasses, or indirectly by the herdsman whose domestic animals are fed chiefly on the same food. Nor must we forget that almost every one of our domesticated animals has been derived from the gregarious types just mentioned, which have accepted the leadership of man in place of that of their own species.

It is perhaps not too much to say that the magnificent outburst of energy put out by the earth in the erection of the Alps, Andes and Himalayas in Tertiary times, was trivial in its influence for man's advent and his successful occupation of the earth in comparison with the gentle but insidious growth of "mere unconquerable grass" and its green carpet of "wise turf", which in some form clothes by far the greater part of the land of the globe.

Development of Brain

The kind of developmental reaction of which this is but a single example must clearly have had influence on bodily features other than bones and horns, teeth and claws, speed and strength; and one of the most striking has been on intellectual development and the size and shape of brain.

We do not, and perhaps can never, know the quality of the material of which the brains of fossil creatures was made, for we have no instrument to pierce the veil of time as the spectroscope has penetrated the abysm of space. But we are even now learning something about their shapes and convolutions, and more about their mass in its relation to the size of the bodies controlled; from the time of the earliest Ordovician fishes, through the history of the amphibia, reptiles, birds and mammals, up to man himself.

The brain of those gigantic if somewhat grotesque reptiles the dinosaurs, the tyrants of Mesozoic time, was relatively tiny. In *Diplodocus*, 80 feet in length and 20 tons in weight, the brain was about the size of a large hen's egg. It is true that there was a big supplementary sacral ganglion which may have taken chief charge of locomotion and helped to secure co-ordination throughout the hinder part of its huge length and bulk; but of true brain there was not more than a quarter of an ounce to control each ton of body and limb; and we begin to understand why they lost the lordship of creation.

The proportion of brain to body improved in those reptiles which took to flying, possibly in relation to their acquisition of warm blood, and in the birds evolved from reptiles; but it is only in mammals that a marked advance is seen. Here the brain of *Uintatherium*, a great rhinoceros-like animal of Eocene date, weighing 2 tons, was about the size of that of a dog. This proportion of half a pound of brain to each ton of body shows how far the mammals had gone, and still had to go. A twelve-stone man of the present day has about $3\frac{1}{2}$ pounds of brain—an amount not far short of half a hundredweight per ton.

Even though we can know nothing of its material, this steadfast growth in the guiding principle, through the millions of centuries that have gone to its development, is surely one of the most remarkable conclusions that we owe to geology. Of all the wonders of the universe of which we have present knowledge, from the electron to the atom, from the virus and bacillus to the oak and the elephant, from the tiniest meteor to the most magnificent nebula, surely there is nothing to surpass the brain of man. An instrument capable of controlling every thought and action of the human body, the most intricate and efficient piece of mechanism ever devised; of piercing the secrets and defining the laws of Nature; of recording and recalling every adventure of the individual from his cradle to his grave; of inspiring or of ruling great masses of mankind; of producing all the gems of speech and song, of poetry and art, that adorn the world, all the thoughts of philosophy and all the triumphs of imagination and insight: it is indeed the greatest marvel of all.

When we contemplate the time and energy, the sacrifice and devotion, that this evolution has cost, we must feel that we are still far from the end of this mighty purpose: that we can confidently look forward to the further advance which alone could justify the design and skill lavished on this great task throughout the golden ages that have gone.

Summaries of Addresses of Presidents of Sections*

The Story of Isotopes

IN his presidential address to Section A (Mathematical and Physical Sciences), Dr. F. W. Aston says that the isotope chapter in the history of science contains much to interest the philosopher and offers many illustrations of that interplay of theory and experiment by which advance takes place. The postulate of Dalton that atoms of the same element are equal in weight was practically undisputed for more than a hundred years. It was correctly preferred to the alternative hypothesis of Prout. Early objections to the postulate were founded upon inaccurate data, and it was only disproved after the discovery of radioactivity.

Soddy's hypothesis of 'isotopes' was at first strongly resisted. Satisfactory proof of it from radioactive evidence could only be obtained in the case of lead, and this was established by chemical results during the War. The possibility that it could be applied to elements in general was first suggested by the twin parabolas of neon, and was proved by the results of the mass-spectrograph. The first of these instruments showed that neon and chlorine each consisted of two isotopes, that krypton had six, and other elements even more. By its means the 'whole number rule' of atomic mass was established and some fifty elements analysed. The difficulties of obtaining the rays for analysis varies enormously from element to element, but during the past fifteen years, knowledge of the isotopic constitution of the elements has become very complete. A year ago, data on all but four had been obtained, and since then the rays of three of these, produced by a new method, have been analysed by Dempster. Iridium is the only one now left. In all, some 259 stable isotopes are known. Elements of odd atomic number do not in general have more than two components but even elements are not so limited, the most complex, tin, having eleven.

One of the most astonishing results is that for practically every natural number up to 210 a stable atom is known. The determination of the relative abundance of isotopes in an element enables its atomic weight to be calculated. This has been done for nearly all the elements, giving valuable checks on the results obtained by chemical means.

The most important work now going on in this field is the measurement of the 'isotopic weights' of atoms. In recent years the accuracy has approached 1 in 10,000, but for theoretical considerations of nuclear structure and artificial transmutation even greater accuracy is desired. The first value obtained for the isotopic weight of hydrogen and the subsequent discovery of the heavy isotopes of oxygen suggested that hydrogen had a heavy isotope. This was discovered by Urey and called deuterium. It cannot be treated as a normal isotope, for its exceptional difference in mass enables it to be separated in a pure state. It has recently been used in the mass-spectrograph to give a more direct and reliable measurement of the isotopic weight of ordinary hydrogen, with the paradoxical result of removing the very discrepancy which led to its discovery.

* The collected presidential addresses at Norwich are being published under the title, "The Advancement of Science, 1935". (Norwich: B.A. Reception Room. London: Burlington House.) 3s. 6d.

Molecular Structure of Carbohydrates

PROF. W. N. HAWORTH'S presidential address to Section B (Chemistry) deals with the molecular structure of carbohydrates. Ten years have elapsed since the structural model of glucose was first presented as the six-atom ring form, an observation communicated to NATURE in 1925. This model now can be regarded as the unit of the carbohydrates cellulose, starch and glycogen. At the outset it was essential to investigate the mode of union of pairs of glucose units which occur in cellobiose and maltose, the bioses to which cellulose and starch give rise by graded breakdown processes. This occurs through the groups at the first carbon atom in one residue and the fourth carbon atom in a second residue, which furnish the oxygen bond uniting two glucose units in these bioses. The spatial disposition of this bond provides the reason for the different identities of starch and cellulose. In other carbohydrates the linking follows a different choice.

Investigations have demonstrated how cellobiose units are united in a continuous chain in cellulose, and how maltose units are assembled in starch. The chain lengths of these and other representative carbohydrates have been determined by the chemical assay of one of the terminal groups in the fully methylated polysaccharides.

A distinction is drawn between the chemical molecule, representing the assembly of glucose units by principal valencies, and the physical aggregate, which has much larger dimensions. Starch has a molecular weight of about 4000–5000, but this

chemical unit is capable of undergoing very considerable molecular aggregation, and these physical aggregates are undoubtedly very complex. Probably the same kind of interpretation should be applied also to cellulose. The aggregation of the chemical unit consisting of about two hundred glucose units may proceed to very great lengths of chain by co-ordination, and there is no doubt that the physical unit of cellulose is dimensionally very large. In this connexion lichenin has been simultaneously studied and its chain length determined. Its relationship to cellulose is similar to that between glycogen and starch.

Glycogen has a chemical molecule represented by a chain of twelve to eighteen α-glucopyranose units. This is smaller than that of vegetable starch, and the tendency to undergo molecular aggregation is not nearly so marked. Investigation of many degraded forms of starch representing different chain lengths has proved of service in the study of this problem.

New carbohydrates prepared artificially by the aid of moulds acting on glucose have resulted in the discovery of new modes of linking of hexose units. The chain length of several of these representatives is short and corresponds to about ten hexose residues. A new polysaccharide from grass, a levan, is found to be composed of ten fructose members united through positions 2 and 6, whereas inulin consists of about thirty fructofuranose units united through the positions 1 and 2.

Considerable interest is attached to investigations on the constitution of gums. A derivative of gum arabic is shown to possess properties resembling the specific polysaccharide of type III pneumococcus serum. Nothing could be more important than the development of the more recent discoveries of polysaccharides possessing immunological functions. A knowledge of their composition, properties and intimate structure will be of immense service to medicine.

Geological Research on Coal

SPEAKING of the state of knowledge at the commencement of this century regarding the real nature of coal, Prof. H. G. A. Hickling in his presidential address to Section C (Geology) says that it was a remarkable example of the tendency of research to pass over 'common' things, and also a striking illustration of the limitations of mere description to convey effective impressions of unfamiliar objects. A review of the writings of various earlier investigators of the last century in the light of present-day knowledge shows that, in their attempts to examine the structure of coal under the microscope, they had seen many of the features which have been revealed by the work of the past thirty years; but, on account of lack of effective illustration, and as a result of their inability to give correct interpretations of much of what they saw, their observations bore little fruit. Coal was still regarded as essentially one substance, and there was no sound basis for a classification of the different varieties, the existence of which the coal-user had perforce to recognise.

Recent work has brought vividly to light the fact that every piece of coal is a complex agglomeration of many different types of plant material; of the residues of wood and cellulose and proteins; of resins, waxes, gums and other substances. The development of microscopic technique has made it possible to show that almost the whole of the coal consists of larger or smaller plant fragments the original component materials of which still exist as discrete masses retaining their original forms, however much or little their ultimate compositions may have been severally modified. The microscope reveals, further, that while every coal is an aggregate, the ingredients differ widely in character and in proportions in different seams, and in different portions of the same seam. Modern research makes it increasingly clear that the problem of the classification of coals is twofold; to divide up the coals according to the nature of the original aggregates of plant debris from which each was formed; and, secondly, to determine the nature and extent of the chemical alteration which the aggregate has suffered after its entombment in the earth. The former determines the *type* of coal; the latter, its *rank*. Its economic qualities depend on both.

Hitherto, chemical examination of coal has been almost entirely confined to analysis of the whole mass, so that variations of composition due to type and rank respectively have not been distinguished; and the order which emerges from comparison of the analyses results only from the fact that, in the more common coals, the general constitution of the aggregate of plant debris is comparatively constant. The outstanding differences are consequently those due to rank. Extended study of the distribution of rank in its relation to the relative depth of different seams, and of the changes of rank exhibited by the various seams as they are traced through the coalfields, is making it increasingly clear that these changes are the result of varying temperatures and pressures to which the coals have been subjected in the earth's crust. Coal is far more sensitive to such changes than any other rock, and may well come in future to serve as the most delicate earth thermometer. Not only for such applications to purely scientific ends, however,

but also equally to provide the knowledge on which we must base any sound practice for the most effective utilisation of coal, it is essential to undertake a far more fundamental study of this mineral, and in particular to investigate separately the many components of the coal aggregate.

The Species Problem

MAINLY from a study of the water-beetles, Prof. F. Balfour-Browne has come to some conclusions as to the origin of species by means of natural selection which he brings forward in his presidential address to Section D (Zoology). He points out that, although a struggle for existence undoubtedly occurs, choice also plays a part in the formation of different communities of water-beetles associated with different types of habitat, and that even localisation under particular climatic conditions is probably partly due to choice.

Choice of a particular food-plant by certain individuals of a species may give rise to biological races, such as are known to exist in Nature and can be produced artificially, and such races may be one source of origin of new species. In any group, species are variously related, some being very distinct while others form clusters and are difficult to distinguish. The clustered species are not usually members of the same community and may perhaps be accounted for on the assumption that they originated as biological races. As to these clusters, there seems to be no evidence that the distinctive characters are hereditary, and it seems possible that they are merely due to the effect of environment upon each succeeding generation.

The majority of the species-characters by which the water-beetles are separated are non-vital and cannot therefore have evolved through the action of natural selection. In some cases the structure is common to other groups but the function is different. The clubbed antennæ found in Hydrophilidæ have appeared several times in the Coleoptera, but if they had been wiped out in all these other groups before the Hydrophilidæ were first studied, we should doubtless be describing them as specially evolved in connexion with respiration in these beetles.

Among these species-characters it is possible to trace what might be called stages in their evolution running through whole groups or families, suggesting that, just as growth is a definite property of the organism, so evolution is an inherent property of the species. But the discoveries in connexion with chromosome control of characters suggest that possibly what has been described as orthogenesis may be the result of mutations caused by external stimuli or, if function can produce an alteration of structure, physiological activities may produce these lines of evolution on the assumption, still requiring proof, that acquired characters are inherited. The inheritance of acquired characters must also depend upon the ultimate effect of changes of habit, physiological activity and structure upon the germ-cell chromosomes, so that the real struggle for existence seems to be in these latter, the first function of which is to see that like produces like, while external influences are perpetually endeavouring to prevent them carrying out their duty.

Polar Research

IN his presidential address to Section E (Geography) Prof. F. Debenham discusses "Some Aspects of the Polar Regions". In spite of an extensive literature on the exploration of the polar regions, there are few sources for a general appreciation of their value to man. The economic aspect is perhaps the best known, since most expeditions of the past have been prompted to some extent by hopes of making discoveries which would ultimately return a profit. Several of the earlier resources, however, were speedily exhausted by the spirit of competition which ruled amongst the different nations. The disappearance of the arctic whale and the reduction in numbers of the fur seal are two instances of this.

Among the potential values that yet remain to be exploited in the polar regions, there is the prospect of using them for air routes. Prof. Debenham urges caution as to acceptance of the exaggerated accounts of possible mineral wealth, especially in the Antarctic. Although by analogy with other parts of the world there are doubtless valuable deposits of precious metals, the almost universal covering of ice prevents prospecting and would hinder mining operations.

The economic aspects of the lands in high latitudes naturally lead to the subject of the national ownership of polar lands and the unusual conditions in which claims have to be made. In the Antarctic, in particular, there can be no occupation, and it seems that its place as a reason for territorial rights will have to be taken by exploration and investigation.

The polar regions are of interest as a field for adventure, and also, in the more accessible parts, as a resort for holidays. So far as Europe is concerned, however, the field is narrowed down to little more of the Arctic than the Svalbard (Spitsbergen) group of islands. Associated with this aspect is another which may yet prove to be of greater value than any other. The polar regions

are, so far as disease is concerned, the most healthy segments of the earth's surface. This is due to the simple fact that most of the disease-bearing organisms cannot live throughout the year in the low temperatures typical of those regions. It is reasonable to suppose that residence in those latitudes should be able to effect a cure for many of those diseases which depend on germs or are spread by infection. There have been some remarkable cases of complete cures from pulmonary affections in the case of members of expeditions. How far this would be true in the cases of actual patients remains to be proved. Medical faculties and foundations such as that of the Rockefeller Institute, whose business is the study of remedial medicine, are urged to endow and carry out research into these possibilities. There seems to be difficulty in securing endowment for such an investigation, which might be of permanent benefit to the sufferers of temperate lands, although there has been heavy expenditure of money on recent flights to the poles.

Examining the value to science of research in the polar regions, Prof. Debenham is of opinion that probably the science of meteorology has most to gain from a continuance of such co-operative work as was carried out in 1882 and 1932, and he commends the natural inclination of young men to visit the polar regions in search of either adventure or results of scientific interest.

Economic Nationalism and International Trade

THE presidential address to Section F (Economics and Statistics) by Prof. J. G. Smith discusses the problems created in the field of international trade by the great accentuation of economic nationalism which has taken place throughout the world owing to the trade depression in the past five or six years. He points out that this policy of economic self-sufficiency is not a new one and that there may be something to be said for a moderate dose of it, especially in countries the history of whose economic development is different from that of Great Britain.

There are two sets of broad influences to be considered which make for economic nationalism or autarchy: those due to the War and to the economic upheaval resulting from the War, and those due to what may be called long-term changes consequent on progress and on scientific invention applied to industry and to commerce. Among the latter are improvements in agricultural technique, which have removed the fears of food scarcity in industrial areas that were once a dominant factor making for freedom of trade, and the development of intricate machine tools, growth of technical education and wide distribution of electrical power, which enable new industries to be set up with equal prospects of success almost anywhere. Again, the vulnerability of modern large-scale rationalised industries causes a struggle for markets (in which Governments are necessarily involved) and high protection for the home market, which is the only one capable of effective control. Further, nationalism which originally had merely political aims has now changed its character and become largely an economic movement. Government control of the whole of economic activity exists already in the three totalitarian States of Europe; and Government regulation is growing rapidly even in such liberal States as France and Great Britain; while recent experience in the United States of America is very significant.

The short-term influences due to the War and to the depression have reinforced powerfully these longer-term movements. Undue concern about the balance of trade, the exact significance of which is frequently misconceived, has led to curious consequences. Quotas, control of foreign exchange, prohibitions of imports, originally designed with one object, have been developed for other purposes. The general result has been a diminution in the volume of international trade which is felt especially severely by a country in the position of Great Britain. It is probable that the desire on the part of Governments to exercise quantitative detailed control over foreign trade may disappear when the depression passes and that these short-term influences making for economic nationalism will lose their force; but it is unlikely that freedom of international exchange will soon return.

Prof. Smith considers the general policy most likely to help in the eradication of these more extreme influences and comes to the conclusion that, as they are due very largely to the instability of currencies and the unforeseen and violent movements of prices which always accompany unstable standards of value, the remedy is to be found in currency stabilisation. This, he considers, can only be attained by a return to a gold standard of some form or other. On the whole, he favours an early decision to link again with gold; for the refusal to act soon will tend to accentuate the difficulties which will be encountered when postponement can no longer be avoided.

Stability in Engineering

IN his presidential address to Section G (Engineering), Mr. J. S. Wilson, a practising civil engineer, has chosen to discuss a branch of engineering to which he has devoted much of his

time. The word stability as applied to a structure means, in a general sense, strength and endurance to resist the loads and forces to which the structure may be subjected. The loads and thrusts combined with the dead weight of the structure induce stresses and strains in the material of which it is built. The determination of these stresses and strains in the various members is a matter of calculation or applied mechanics. The maximum stresses allowed in the members must be chosen to suit the characteristics of the material used.

Thus there are two sides to all problems in stability. Great advances in both have been made during the last hundred years by the more extended use of mathematics or applied mechanics on one side and in the testing and improvement of materials and methods of construction on the other.

Three interesting episodes in the history of the subject are recalled. The first of these relates to the arch. Our knowledge of the stability of this form of structure was in a state of confusion up to the middle of the nineteenth century, when efforts to advance appear to have been more a matter of dialectics than of science or experiment. The sharp differences of opinion on principles of design on the part of those who wrote with authority on the subject led engineers and architects who actually built arches to take extraordinary precautions to ensure their stability. Reference is made to Dr. Johnson's views on the relative strengths of semicircular and elliptical arches.

The feeling of uncertainty regarding the stability of masonry dams which arose at the beginning of the century and the re-establishment of confidence in the methods of calculation previously accepted form the second episode. Experimental investigations with the aid of india-rubber models on the distribution of stress in dams, which were carried out by the late Mr. William Gore and Mr. Wilson, helped to clear up the uncertainty.

The third relates to suspension bridges and the introduction, in 1836, of Dredge's patent taper chain principle of design. Designs on the new principle were very economical in the amount of iron needed and those who advocated the adoption of the principle were powerful. The principle was fundamentally unsound and although it was criticised, engineers and applied mathematicians of the day were too uncertain, or commanded too little support, to be able to shake confidence in it, and a large number of bridges were built in Great Britain and in India. The first ones had some margin of stability by good luck rather than design, but the later ones failed either before completion or soon after.

These three episodes reflect on the advances made in our knowledge on the applied mechanics side of the problem of stability. With regard to the permissible or working stress side, on which the more economical use of material depends, progress has not been so rapid.

The Birthplace of Man

SIR ARTHUR SMITH WOODWARD'S presidential address to Section H (Anthropology) is an account of recent progress in the study of early man. Palæontology and geology contribute much to our understanding of prehistoric archæology. It has long been recognised that the earliest men of which traces have been found in Europe did not originate on this continent but were immigrants from some other region. It is therefore important to examine the numerous associated mammals to ascertain whence they came; for most of these mammals seem also to have been immigrants to Europe just before or during the Pleistocene period when man began to live here, and they may give a clue to his origins. These mammals show that when they flourished in Europe, the only direct land communication with the rest of the world was through Asia. The supposed connexions with Africa by way of Sicily and Malta and by Gibraltar have now been disproved. New discoveries of fossil mammals in the caves of Palestine and Syria show that during the early half of the Pleistocene period, Asia and North Africa were much more closely connected than they have been since. The explanation of the partial identity between the Pleistocene mammals of Africa and Europe is probably, therefore, that they had a common source in Asia.

Although the succession of stone implements in Pleistocene deposits in Africa is nearly the same as that in Europe, there is no evidence so far that the oldest types were made by the same primitive men. It is, however, now very doubtful whether the earliest tools in Kenya Colony were made by a modern race of men, as claimed by Dr. L. S. B. Leakey. The only fossil remains of man hitherto found in Africa seem to be related either to the surviving South African bushman or to the Australians.

The only known fossil which suggests that Africa may have produced man is the immature skull of an ape from Taungs in Bechuanaland, which was named *Australopithecus* by Prof. Raymond Dart. Numerous teeth and jaws of apes related to the chimpanzee are now being found in the Miocene of south-east Africa; but

teeth and jaws of apes, with perhaps still more human characters, are abundant in the Mio-Pliocene deposits of northern India. Indeed, the theory that man arose in central Asia from ground apes, which had been driven from the forests by the upheaval of the Himalayas, is still the best which has been proposed.

Man had reached the stage of *Homo sapiens* before he crossed the narrow seas from Asia to Australia. The fossils *H. wadjakensis* and *H. soloensis* from Java, and some fossil skulls from South Africa seem to represent his forerunners on the mainland.

H. sapiens, who had already learned the art of trimming stone by pressure flaking, seems to have been the first human immigrant to America by way of Bering Straits. Late palæolithic stone implements like those found in the Gobi desert were discovered last year in Alaska. Implements much like those of the Solutrean stage in Europe have now been found in several localities in the southern United States in association with extinct mammals of Pleistocene age. Human remains were first found directly associated with extinct mammals in South American caves by the Danish naturalist, P. W. Lund, whose centenary has just been celebrated by the scientific men of Brazil in Minas Geraes.

The Pituitary Gland

THE anatomical and physiological connexion between the pituitary and diencephalon form the subject of Prof. P. T. Herring's presidential address to Section I (Physiology). The diencephalon itself is the site of integration of nervous impulses concerned in the regulation of many of the fundamental processes of life. The pituitary body is the only one of the diverse structures of the diencephalon which receives an accession of epithelium from an outside source—the buccal epithelium. These epithelial elements of the pituitary form one of the most important structures of the diencephalon.

The pituitary body provides the brain with an armamentarium of hormones, which are secreted in several ways. Quite a large number of hormones are now allocated to the pituitary, and more may be discovered. Some of these exert their actions directly upon peripheral tissues through the blood stream; others act locally upon nervous mechanisms in the hypothalamus. All are under the control of this part of the brain.

From the anterior lobe are secreted hormones which stimulate growth and exercise a controlling influence over the gonads, thyroid, parathyroids, thymus, cortex of the suprarenals and the mammary glands. Some also influence metabolism, especially of carbohydrate and fat.

Pituitrin, an extract of the posterior lobe, has so far been separated into two fractions. One has a pressor effect. There are, however, anomalies in its action. It is also considered that the secretion of the posterior lobe is essential for the preservation of capillary tone. The other portion of pituitrin acts upon uterine muscle. The relationship of the secretion of the posterior lobe to the metabolism of carbohydrate and of fat is still obscure. Many other activities of the posterior lobe have been described and postulated, but one may well question if all be normal functions.

Nevertheless, one is compelled to conclude that the active principles of the pituitary are such as are necessary for the regulation of common and fundamental processes in the life of the animal. The diencephalon and pituitary body form a working unit, and have far-reaching importance in the control of fundamental physiological processes. It is probable that the pineal body is another part of the same mechanism, but its functions are still to be discovered.

Personality and Age

IN his presidential address to Section J (Psychology) on this subject, Dr. Ll. Wynn Jones directs attention to recent investigations with adult subjects. Most of the psychological measurements of the present century have been concerned with the mental traits of the child or the adolescent. Until recently, the later decades of human life had not been systematically studied. Adult populations are relatively inaccessible, the selection of samples presents statistical difficulties, and it is not easy to differentiate between what is largely native and what is largely acquired. Nevertheless, by the use of questionnaires, introspections, biographies, as well as various psychological tests, there has recently accumulated a mass of objective data concerning adults, resulting from the work of such investigators as Profs. Charlotte Bühler, Giese, Catherine and Walter R. Miles, Edward K. Strong, Terman, and Thorndike.

In brief, the effect of age, as such, on the ability to learn and, indeed, on most psychological abilities, is much less than has been generally supposed, not only up to middle age but even up to old age. It is true that elderly individuals, who still consider their powers to be at their zenith, may be objects of pity, but still more so, it would seem, are those who consider their abilities to have deteriorated long before that is actually the

case. Thorndike concluded that, in general, nobody under forty-five years of age should restrain himself from trying to learn anything because of a belief that he is too old to be able to learn it. For example, the facts are in flat contradiction to the doctrine that childhood is the period when it is easiest to learn to read, write or understand the hearing of a language. Similarly, objective tests of various sensory and motor and also of the more intellectual abilities show that the differences between old and young are small in comparison with the differences within either group.

Such findings have obvious applications to schemes of adult education or to the training of the unemployed. Ancient customs and opinions which had little scientific backing have in the past made it difficult for many of the unemployed to embark on any training for a new career. In industry it is especially important to obtain objective information regarding the handicaps of older workers. Age alone as a criterion for displacement or retirement is in many cases quite inadequate.

The question of age also arises in athletics. The ability of a sprint runner, which demands maximum expenditure of energy per second, is probably at its best at about twenty-three or twenty-four years of age. The half-miler must also learn economy of effort and its proper distribution, and his ability is at its maximum a year or two later. Much later are the maxima in sports requiring not only economy of effort but also the technique which only comes after long experience. Thus the median age of batsmen who have exceeded 3,000 runs in a season is 34·5 years; and the forty golfers who headed the Open Championship list in 1934 show a median of thirty-five years.

There are certain theoretical implications of these observations. Now that factorial analysis is proving so potent a method in psychology, it becomes necessary to study age in relation to personality more systematically. This will determine the relative importance of the various unitary traits at different stages of life, and this, in turn, will lead to a fuller psychological interpretation of the traits themselves.

Plant Pathology

MR. F. T. BROOKS'S presidential address to Section K (Botany) discusses certain aspects of recent investigations on disease in plants. With the discovery of the Mendelian inheritance of disease resistance, a potent weapon was placed in the hands of geneticists and pathologists for the control of plant diseases. Although sometimes very successful, the breeding of disease-resistant varieties cannot be looked upon as a panacea for the elimination of disease: great difficulties are sometimes experienced in building up these types, especially on account of the several diseases to which most crop plants are liable and the close linkage which often exists between a valuable quality and susceptibility to a particular disease; furthermore, progress along these lines with arborescent plants is necessarily slow. On the other hand, certain diseases can be effectively controlled either by paying due attention to environmental conditions which favour the host at the expense of the parasite, by the eradication of the sources of infection in accordance with the principles of plant sanitation, or by fungicidal treatment.

The influence of environment on the establishment of disease in plants is of outstanding importance. Environmental conditions which are most beneficial to the host frequently prevent attack by weak parasites. With fungi such as the rusts and downy mildews, however, optimum conditions for the host are often equally favourable to the parasite.

Much progress has recently been made in the study of the epidemiology of certain parasitic diseases, that is, the distribution in space and time of the causative micro-organisms which develop epidemically under favourable conditions. For example, in North America, Australia and India, an almost complete explanation is now available of the manner in which epidemics of black rust of cereals (*Puccinia graminis*) arise.

There are many physiologic or biologic forms within single species of parasitic fungi, especially in the rusts, a state of affairs which may greatly complicate the task of producing disease-resistant varieties. How these forms with different parasitic proclivities have arisen is an intriguing problem. It is known that sexual interactions between diverse forms may be the means of adding to their number, but it is suggested that gene mutation has also been a potent factor in their development. Although, in general, these physiologic forms are stable entities, their capacity for evolutionary change must not be forgotten.

Another active branch of plant pathology is that concerning the influence of one micro-organism on another in the establishment of disease. A host attacked by one fungus may thereby be rendered more susceptible to another, and a plant permeated by a complex of two viruses may exhibit symptoms unlike those induced by either virus acting separately. On the other hand, the effect of micro-organisms on one another may be one of antagonism. Of particular interest and of great importance is the antagonism shown by certain saprophytes to pathogenic fungi which invade the

underground parts of their hosts: indeed it is not too much to say that a new chapter in soil microbiology has been opened with the recognition of this factor of biological antagonism. The pathogenicity of fungi which cause foot-rot of cereals may be completely suppressed by the antagonistic influence of soil saprophytes, either through the secretion of some toxic substance or perhaps by the stress of competition. When more is known about the antagonism of other micro-organisms to pathogenic fungi in the soil, it may be possible to devise methods of biological control, such, for example, as altering soil conditions so as to favour the antagonistic action of other members of the micro-flora.

The Schools and Citizenship

DR. A. W. PICKARD-CAMBRIDGE has chosen "Education and Freedom" as the title of his presidential address to Section L (Educational Science). In Germany, Italy and Russia the suppression of freedom is largely carried out by the control of education, of which the aim is to teach the individual not to think. If freedom is to be maintained, it can only be by an education designed to teach the young to think freely and accurately, and to act as responsible citizens of democracy. The ideal community will be one which allows all to take a share in the formation of public opinion (and trains them to do so), and in which no one is simply a means to the ends of others, but each is free to realise the highest values and able to make his contribution to the common good. In the individual life, freedom, which is at first possessed only in a small measure, cannot usually be acquired without discipline and the presentation of the higher values by authority, and one function of education is to give the young a chance of appreciating these higher values, both by suggestion and example, and also in school work, for example, in the study of literature and history and the much-neglected study of the Bible.

Another function is to produce the habit of clear and accurate thinking. For this a citizen needs in later life access to the facts about which he is to form judgments, and this (as the popular Press is at present) is hard to obtain. In his education he should have practice in forming judgments upon evidence, and in all his work there should be insistence on individual thinking, not on mere absorption of lessons or rules-of-thumb. In many of the secondary schools of Great Britain—which are the key to the situation, since from them will come most of the teachers of the mass of the people and the leaders of opinion in most of the smaller circles in which public opinion is made—more practice might be given to the pupils in the management of their own affairs out of school, and in activities which encourage self-expression.

Examinations as at present treated in schools, largely owing to the excessive stress laid upon them by education authorities and employers, are serious obstacles to the acquisition of freedom and independence of mind, and here serious reforms are necessary. Other reforms, such as the prolonging of the time of education and the reduction of the size of classes, are urgently required, if the young citizens' capacity for freedom and for the citizenship of a free State are to be developed. All educational institutions and methods must be tested at every point by their tendency to produce or to hinder such freedom, and everything eliminated that makes for the standardisation of individuality or is hostile to ultimate independence of judgment, while at the same time the higher values (which make for good life and good citizenship) are so presented to the young that they may have the chance of freely making them their own.

State Control in Agriculture

IN his presidential address to Section M (Agriculture), Dr. J. A. Venn discusses the "Financial and Economic Results of State Control in Agriculture". A rather full criticism is made of agricultural economics and organisation from the end of the Napoleonic wars, until the beginning of the Great War—including that "period of rural depression of the 'nineties . . ." which finally passed "without affecting either the National outlook or the National purse".

The War years were a period of rigid control, and are therefore not considered. The present period began in 1922. The cost to the State of reliefs and disbursements are estimated. For example, the subsidising of sugar and molasses derived from home-grown sugar beet has been, during eleven years, slightly more than £47,000,000. The Forestry Commission will, in fifteen years, have expended £6,000,000. Non-returnable State contribution to the Milk Marketing Board amounted in 1934–35 to £1,600,000, and within a year £2,924,000 have been expended on the beef subsidy. Reliefs from rating must represent some £15,000,000 annually.

Recent tendencies involve a slight increase in output of the soil, a decline in arable area, a transference from production of feeding-stuffs to

that of sale crops, a reduction in number of workers, and a redistribution between the different classes of livestock. Of the expenditure that these results have involved, landowners have directly received little, and continued to deteriorate. Tenant-farmers have partly bridged a gap to save them from impotence as producers; while rural workers have received an increase of 75 per cent in wages. Recent 'planned' agriculture gives a figure of £40,000,000 in annual benefits derived from grants, remissions and augmented prices. It is arguable to what extent the middlemen's returns have been affected; but it may concern intimately the consumer. The direct tax-payer has gained a measure of respite, at the expense of the indirect.

A vast change has occurred in the problems of agriculture during the past hundred years, and consideration has ousted severity, and preferential treatment superseded laissez-faire. Agriculturists are faced with the twin problems of over-production and under-consumption. The most recent proposals involve a movement from quotas to levies, with a modicum of Dominion preference. Nevertheless, British agriculture has gained a protective covering to shield it from the worst economic shocks. But this may actually hamper it when progressing over the smoother terrain of normality which it is hoped lies ahead. Possibly the near future will witness some relaxation from control and some restoration of individual liberty of action.

Preservation of Sites of Scientific Interest

PROF. P. G. H. BOSWELL'S presidential address to the Conference of Delegates of Corresponding Societies deals with the preservation of sites of scientific interest in relation to town and country planning. One of the most enlightened enactments placed upon the Statute Book for a long time is the Town and Country Planning Act of 1932, wherein it is laid down that a local authority or joint committee must obtain the approval of the Ministry of Health before it can implement any resolution relating to a scheme of planning. Among the objects of such a scheme, as cited in Section 1 of the Act, are "preserving existing buildings or other objects of architectural, historic and artistic interest, and places of natural interest or beauty, and generally of protecting existing amenities whether in urban or rural portions of the area".

Formerly, the success of efforts directed to the preservation of sites and objects of scientific interest was due to the enthusiasm of advocates, and the broadmindedness and public spirit of landowners and benefactors. While this good work will, it is hoped, still continue, much more power is now in the hands of the people. But, as ever, knowledge is a prerequisite of useful action. How can the British Association, and in particular the Corresponding Societies, inform the people and assist them to safeguard their natural heritage?

Judging from the frequency of references to this and to cognate subjects in the columns of the daily Press, there can be no doubt as to the public awareness of the desirability and necessity for preserving sites and objects of scientific interest and natural beauty. The Ministry of Health has given opportunity to the Association to advise as to when action ought to be taken—that is, to conserve, concentrate and direct energy which might otherwise be dissipated in isolated action or unprofitable controversy. The areas in which planning schemes are proposed are notified to the British Association, a body admittedly well-fitted to advise the Ministry, by its aims and constitution, by its liaison with the Corresponding Societies, and by the call it can make upon scientific experts within and without its ranks.

Obviously, before the Association can act effectively, the requisite information regarding the existence of objects and sites worthy of preservation must be available. So far as botany and zoology are concerned, no systematic attempt to compile a list appears to have been made, but in the case of geology an inquiry was instituted some years ago by the Geological Society among local geologists and learned societies, with the result that a valuable though incomplete list was drawn up. In order to make the list as complete as possible, the Association is in a position to call to its assistance (*a*) its Corresponding Societies and their delegates; (*b*) the specialist learned societies; (*c*) officials of local museums and libraries; and (*d*) teachers in universities, colleges, and in public, grammar, secondary and technical schools. The reference list which may thus be compiled will be available for consultation as each scheme of planning is notified; and where there is doubt as to the best policy to pursue, the advice of experts on the panel already drawn up for the purpose by the Council can be sought.

Details are given of sites of scientific interest which should be preserved (*a*) in the area of Darwin's home at Downe, now held in trust by the British Association, and (*b*) in East Anglia.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

other. It helps also in the search for methods to control abnormal growth: the action of radium on a tissue culture can show how it may be used most effectively in the treatment of cancer. The director's Report gives brief abstracts of the different researches at present in progress.

Imperial Agricultural Bureaux

THE fifth annual report (1933–34) of the Executive Council of the Imperial Agricultural Bureaux has now been published (London: H.M. Stationery Office, 4*s*. net). Consequent on the recommendations of the Imperial Committee on Economic Consultation and Co-operation (1933), the Council, in addition to its previous duties, has taken over the administration and financial control of the Imperial Institute of Entomology and of the Imperial Mycological Institute. Special prominence is given in this year's report to the work of these Institutes, and the degree of their activity may be judged by the fact that, on an average, more than 2,000 specimens a week have been received for identification by the former, and material has been forwarded from thirty-five Dominions and Colonies to the latter Institute during the year under review. The parasite laboratory at Farnham Royal, started by the Empire Marketing Board, has also passed under the control of the Council, and now draws common financial support. The work of the eight original bureaux continues to develop, and increased use is being made of the information services available by research institutes and research workers throughout the Empire.

Madras Fisheries

DR. B. SUNDARA RAJ, director of fisheries, Madras, in his administration report for the year 1933–34 (Madras Fisheries Department), 1934, shows that the outstanding event of the year, which has brought back some measure of prosperity to the fishing industry of the west coast, was the return of the oil sardine in unexpected abundance after an absence almost complete for an unusually long series of years. The oil sardine (*Sardinella longiceps*) is the most important economic fish of the west coast, and its absence had reduced the fishermen to extreme poverty. Its return was just in time to save the industry from extinction, though advantage could not be taken of the abundance of the fish owing to the prevailing economic depression. Samples were examined twice a week and studied in detail. Research in all directions is progressing, an important result being the success obtained in keeping live pearl oysters under artificial conditions at the Krusadai Biological Station. This points to the possibility of establishing an oyster park which is one of the principal aims of this station. Oysterlings of 30–40 mm. have lived in cages well over a year, during which several have grown to almost adult size (50–65 mm.). There is evidence of the larger oysters in the cages having spawned in captivity. Spawn has been found in the cages, and a pycnogonid found swarming in them had young microscopic oyster spat attached to the lateral processes. Special attention is being given to determination of age and rate of growth. Other investigations are in progress including a systematic survey of deep-sea fishing grounds by the trawler, plankton investigations, fish eggs and larvæ, daily collection of food fishes and hydrographical records, whilst technological research is not neglected. The whole report is exceedingly interesting and instructive, showing much activity in all directions.

Literature of Food Investigation

THE first number of vol. 6 of the "Index to the Literature of Food Investigation" reviews the developments during the years 1932–33 (Department of Scientific and Industrial Research: Index to the Literature of Food Investigation: Vol. 6, No. 1, March 1934. Compiled by Agnes Elisabeth Glennie, assisted by Owen Davies. London: H.M. Stationery Office, 1935. Pp. 309+v. 5*s*. net). One of the most important is the application of gas storage to meat: by increasing the amount of carbon dioxide in the atmosphere to 10–12 per cent, it is possible to keep chilled meat in good condition for about seven weeks, so that chilled, instead of frozen, meat can be brought to Great Britain from so far away as New Zealand. Among other problems relating to animal products to which attention is directed are the onset of rancidity in stored food and the production and use of fish oils, which has assumed increasing importance with the development of our knowledge of the value of vitamins A and D as dietary factors.

HALIBUT liver oil is a rich source of vitamin A, often 50–100 times as rich as cod liver oil: the liver oil of the ling cod may contain about eight times as much vitamin D as cod liver oil: the latter is not present in the liver oils of cartilaginous fish or in the liver fat of whales and other mammals. In the case of milk and milk products, reference is made to the pasteurisation of milk, the effect of processes of manufacture on the solubility of the protein of milk powders and the keeping qualities of butter. Interest continues to be shown in methods of freezing animal and vegetable tissues. Quick freezing has no advantage over slow freezing, so far as the palatability of meat is concerned, nor has it any advantage in the preservation of peaches, strawberries or apple cider. Freezing orange and grapefruit juices does not usually affect the vitamin C potency. The importance of research into the problems of the storage and transport of fruit is shown by the fact that in 1932 more than 100,000 tons of oranges and 7 million bunches of bananas were brought to Great Britain in refrigerated ships, and emphasis is laid on the fact that the most satisfactory method of ascertaining the best storage temperatures for ocean transport is to make precisely controlled storage trials in the country of origin of the fruit.

New 'House Number' Lamps

THE names of the streets round London are usually placed in a conspicuous position and are well lit by some neighbouring lamp, but in some of the side

streets and avenues it is difficult to identify the number of the house. The illumination of these numbers would often be a great boon. In the August number of *Helios*—the German export journal for the electric industry—it is stated that in many newly built suburbs 'number lamps' have been installed over the front doors or in other convenient spots. Several of the older streets also are being equipped with these lamps. Electricity supply companies are encouraging their use by giving the consumer energy for illuminating the lamps at a specially low rate. The number lamps illustrated in the journal are prismatic in shape, three of the edges being vertical and the top and base being horizontal. Expensive shades in opal glass are sometimes used, but owing to the risk of breakage, most people use a cheaper form. Simple panes of glass are put in a cast iron frame. They can be easily removed for cleaning and in the event of an accident the pane can be easily replaced. The transparent number panes are placed in a black frame and the triangular base of the lamp is provided with an opal glass pane which lights up the entrance to the house.

Physics Research at Harvard

Contributions from the Physical Laboratories of Harvard University, vol. 22, is a collection of separate copies of 29 papers which have been issued by the Laboratory during the years 1932–33, bound together and provided with a table of contents. It extends to about five hundred pages, but the pagination of the original memoirs is retained. More than half of the volume is occupied by papers written by Prof. P. W. Bridgman or by workers in his laboratory. They add considerably to our knowledge of the properties of substances under great pressures. A paper by Prof. Bridgman puts forward serious criticisms of some of the methods of proof used in the current theory of groups (*mengenlehre*). Several of the remaining papers issue from the laboratory of Prof. W. Duane, and deal with investigations of atomic and molecular properties, while others dealing with spectroscopic investigations originate in Prof. T. Lyman's laboratory. Two others deal with vapour pressures and entropy, one with the magnetic properties of certain iron alloys, and another with the large changes of ionisation of the atmosphere which are produced by solar eclipses. Readers of these contributions will be struck by the importance of the work which is being done by 'National Research Fellows'.

The Fish and the Ring

THE city of Glasgow bears in its coat of arms a fish with a ring in its mouth, and the incident so commemorated involved a lady's honour in the days of St. Kentigeon. But since rubber rings were invented, the association between fish and ring has become a matter of solid fact. In the *Australian Museum Magazine* of April, G. P. Whitley has collected accounts of curious cases where fishes have become involved in rings, and the examples range from garfish and mackerel with rubber rings surrounding and even partly embedded in their bodies, to a shark, captured at Havana, Cuba (recorded by Dr. Gudger), and adorned by a motor-car tyre which encircled its body and was prevented from slipping over the tail by the dorsal fin and from slipping over the head by the pectorals.

Land Speed Record

SIR MALCOLM CAMPBELL made a new world land-speed record on September 3 by driving his *Bluebird* car on the Bonneville salt flats in Utah at a mean average speed of 301·337 miles per hour. In the first run, he was stated to have covered the measured mile in 11·83 sec., which works out at 304·311 m.p.h. The second run was stated to have been covered in 12·18 sec., giving a speed of 295·566 m.p.h. His average speed was therefore given as 299·875 m.p.h. Later it was announced that there had been a miscalculation of the time, and the average speed was corrected to 301·337 m.p.h.

Announcements

THE autumn meeting of the Institute of Metals will be held at Newcastle-upon-Tyne on September 9–12. The proceedings will begin in the evening with the delivery by Dr. H. W. Brownsdon of the fourteenth annual Autumn Lecture on "Metal Melting: its Effect on Quality". Following the lecture, a general discussion will take place on several different phases of the lecturer's subject. No tickets are required for admission to the lecture, which will be given in the King's Hall, Armstrong College, at 7.15. Visitors are admitted to the business sessions, beginning each morning at 10 a.m., on signing the visitor's book in the New Mining Lecture Theatre, Armstrong College.

A VOLUME of collected researches published from the Wards and Laboratories of the London Hospital during 1934 has been issued (London: H. K. Lewis and Co., Ltd. 7*s*. 6*d*. net). The papers included extend over a wide range of subjects, and mostly embody original observations of importance for the diagnosis, prognosis and treatment of disease.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

An assistant (Grade II) and a junior assistant in radiological research, a junior assistant and two assistants (Grade II) in ballistics research, and an assistant (Grade I), an assistant (Grade II) and a junior assistant in explosives research, in the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S.E.18 (Sept. 14).

A junior scientific officer in the Admiralty Scientific Pool—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (Sept. 21).

An assistant curator of the Museums in Leeds—The Town Clerk, Room 57, Civic Hall, Leeds, 1 (Oct. 7).

A lecturer in mathematics in the University of Tasmania—The Agent-General for Tasmania, Australia House, Strand, London, W.C.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 398.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Charles Darwin and the Galapagos Islands

IT seemed possible that an examination of some of the unpublished Darwin manuscripts dealing with material collected during the weeks spent on the Galapagos Islands might bring fresh light to bear on the much discussed manner of growth of his evolutionary outlook. At what period during the *Beagle* voyage did his views crystallise ?

We know that in 1837 Darwin opened his first notebook on the transmutation of species, and made especial tribute to the Galapagos species as the origin of all his views, together with the South American fossils. But little sign of such a revolution found its way on to paper at the time. I have therefore been fortunate in finding among the contemporary ornithological notes a passage bearing directly on the subject, where the significant phrase "for such facts would undermine the stability of species" occurs. Here we have the earliest date yet obtained, I think, for an admitted upheaval of his thoughts along evolutionary lines. The ferment had already begun to work in September 1835.

As the passage in the manuscript differs widely from what was printed, both in the "Voyage of the *Beagle*" (1870, pp. 394–5), and in the "Birds of the Voyage" (Part 3, "Zoology of the Voyage", 1841, 4to) it may be worth quoting it at greater length.

"*Thenca.* [Mimus Thenca.] These birds are closely allied in appearance to the Thenca of Chile. They are lively, inquisitive, active, *run fast*, frequent houses to pick the meat of the tortoise which is hung up,—sing tolerably well,—are said to build a simple open nest,—are *very* tame, a character in common with other birds. I *imagined*, however, its note or cry was rather different from the Thenca of Chile— ? Are very abundant over the whole Island ; are chiefly tempted up into the high and damp parts by the houses and cleared ground.

"I have specimens from four of the larger Islands ; the specimens from Chatham and Albemarle Isd. appear to be the same, but the other two are different. In each Isd. each kind is *exclusively* found ; habits of all are indistinguishable.

"When I recollect the fact, that from the form of the body, shape of scales and general size, the Spaniards can at once pronounce from which Isd. any tortoise may have been brought :—when I see these Islands in sight of each other and possessed of but a scanty stock of animals, tenanted by these birds but slightly differing in structure and filling the same place in Nature, I must suspect they are only varieties. The only fact of a similar kind of which I am aware is the constant asserted difference between the wolf-like Fox of East and West Falkland Isds.— If there is the slightest foundation for these remarks, the Zoology of Archipelagoes will be well worth examining ; for such facts would undermine the stability of species."

Yet this profound change of view is scarcely discernible in the different editions of "Voyage of the *Beagle*". Even in the second edition of 1845, the words "creation" and "creative force" are used in the Galapagos discussion in the traditional sense. Darwin took no pleasure in overthrowing preconceived doctrines ; he entered the new road cautiously, determined to pave it with solid accumulated evidence. Probably a certain deference to Capt. FitzRoy's views, emphatically creationist, helped to delay the unfolding of Darwin's divergent opinions.

In this respect, FitzRoy's description of the birds of the Archipelago is in interesting contrast to the quotation from Darwin. "All the birds that live on these lava-covered islands have short beaks, very thick at the base, like that of a bull-finch. This appears to be one of those admirable provisions of Infinite Wisdom by which each created thing is adapted to the place for which it was intended. In picking up insects or seeds which lie on hard iron-like lava, the superiority of such beaks over delicate ones, cannot, I think, be doubted. . . ."

It is sad to learn from Ecuadorian sources that the Galapagos Archipelago is no more ; it is now the Archipielago de Colón. Moreover, Chatham Island has become San Cristobal, Hood and Charles are Española and Santa Maria Floreana, whilst Albemarle is Isabella. Perhaps in all truth as fitting a collection of names for the Pacific Ocean as our old ones of British kings, admirals and statesmen ; but saddening to insular tradition.

X-Ray Examination of the Effect of Removing Non-Cellulosic Constituents from Vegetable Fibres

THE cellulose of the cell-wall and fibres of most plants contains closely associated polysaccharide material which is generally a xylan. The cotton hair is unique in being free from xylan, but manilla hemp, jute and sisal, for example, may contain as much as 15–20 per cent. The view has been put forward tentatively that the xylan molecules in such fibres participate in the micelles and are oriented in the same direction as the cellulose chains[1] : the period along the fibre-axis of xylose residues in oriented xylan would be very much the same as that of the glucose residues in cellulose, and their presence should make no fundamental difference to the X-ray photograph. In support of this view there is the well-known fact that actually no such difference is observed in the ordinary way.

In carrying out a more serious test of the hypothesis, we have recently, among other things, examined by X-rays the effect of removing progressively the xylan (initially 19·8 per cent) of cellulose fibres from manilla hemp, using an apparatus specially designed for taking strictly comparable photographs on one and the same film[2]. By this means very accurate comparisons were possible, but again no really fundamental change was revealed. Briefly, it may be said that removing xylan from fibres of high xylan content merely makes their X-ray photographs more like those of fibres of low xylan content! The point of this apparently pointless verdict is that the X-ray photographs of fibres of low xylan content—ramie and Italian hemp, for example—show certain diffraction features typical of a more perfect state of crystallisation. The result of these experiments is therefore definitely in favour of the view that the incorporation of xylan is a sort of mixed crystallisation.

A number of common fibres were also purified by removal of lignin and encrusting hemicelluloses. As would be expected, the effect of this treatment was in general to clarify the X-ray photograph, and in most cases to lead to improved definition through a sharpening of the crystallite orientation. Otherwise, nothing of any great significance was observed. Much depends on the care with which the chemical pre-treatment is carried out, for it is possible to injure the crystallite orientation instead of improving it. Miles Thomas and Hewitt[3] report a diminished *intensity* in photographs of purified fibres; but we have not observed such an effect.

The photographs and experimental details of the work will be published in due course. In the meantime attempts are being made to obtain an X-ray pattern from xylan alone.

Sub-Boundaries in a Crystal Grown by the Bridgman Method

INTEREST in irregularities observable in single crystals has arisen through the large discrepancies between the results of experimental studies of some of the physical properties of crystals and theoretical studies based on the idea of a single uniform lattice extending throughout each single crystal.

An observable irregularity has been found in working with a single crystal of copper grown by the Bridgman method. In trying to get an undistorted section parallel to the 311 planes for use as an X-ray polariser[1] many surfaces had to be cut, etched and examined under the microscope. The appearance of one such section, shown in the photomicrograph (Fig. 1), suggests that the crystal had broken down into a large number of small ones, the outlines of which are seen as the curved lines. The etching had been done with nitric acid, which develops the cube planes, so that the whole surface was covered by tiny cubes each having one corner projecting.

It was noticed that, as nearly as could be judged by eye, not only were the whole of the cubes similarly orientated, as would be expected in a single crystal, but also some of the individual cubes actually crossed the curved boundary lines. Both effects were easily seen distributed over the whole 7 mm. of crystal and they are detectable in the photomicrograph. The arrow is parallel to a cube face. The grinding marks are parallel to the two edges of the page. X-ray photographs showed that if the crystal had broken up into smaller ones, their orientation was unchanged within the limits of the experimental accuracy.

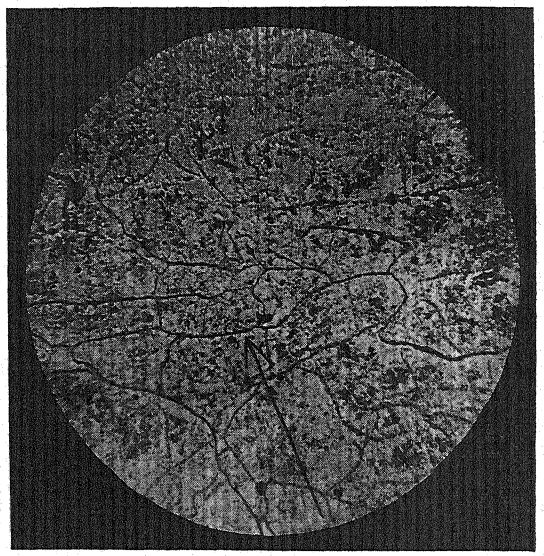

FIG. 1. Etched section of a single crystal copper rod cut parallel to (311) planes showing, to left of arrow, sub-boundaries crossed by cube edges. (× 30.)

Sir Harold Carpenter kindly pointed out that the markings are similar to the 'sub-boundary' or 'veined' structures observed in many metals. In the literature, these have been studied in the individual grains (crystals) of polycrystalline material but their nature is apparently not understood yet. Smithells and Rooksby[2] suggest that the sub-boundaries are formed under the influence of stresses set up during the rapid cooling of the metal (tungsten). Such a hypothesis would be untenable for copper as the observations here reported were made upon a crystal cooled very slowly. Furthermore, Northcott[3] was able to suppress veining in polycrystalline copper by quenching from 1,000° C. The etching which is favourable for revealing sub-boundaries is not always favourable for showing the crystal orientation. In preparing the specimen illustrated, the acid was applied to the clean dry surface held by the side of a running tap, so that the action could be stopped quickly after about one second.

Since these sub-boundaries can be found in single crystals, it is evident that their possible influence upon some physical properties can be studied in types of experiment not possible with polycrystalline material where they have been observed hitherto.

Change of Magnetic Susceptibility of Metals during Melting and Allotropic Transformation

THE change of magnetic susceptibility during allotropic transformation or melting of metals was first observed by one of the present writers[1] about twenty-five years ago, in his measurement of the magnetic susceptibility of pure metals at temperatures ranging from room temperature up to 1,000°. In that paper the remarkable fact was mentioned that the magnetic susceptibility of tin changes its sign twice as the temperature rises. That is, the change of grey tin, which is a strongly diamagnetic substance, into white tin at 18°, is accompanied by an abrupt increase of susceptibility, which becomes thus paramagnetic, and afterwards this susceptibility remains constant up to 232°, at which temperature it resumes its diamagnetic properties on melting. In order to obtain a more accurate value of the susceptibility change during allotropic transformation or melting, we have recently measured the susceptibility in vacuum, and have succeeded in explaining the phenomenon in a quantitative way by applying our former theory[2] which has been proposed to explain the change of susceptibility in metals caused by cold working.

This note contains a preliminary report regarding metals such as tin, copper, silver and gold that show the above phenomenon.

In our theory, we assume that the magnetic susceptibility is affected by the volume change caused by an allotropic change or melting in two different ways: (1) the change of paramagnetic susceptibility due to the diminution of free electrons caused by the expansion; (2) the change of diamagnetic susceptibility due to the increase of bound electrons caused by the expansion. In the case of contraction, the free electrons increase at the cost of bound electrons, and hence the changes due to (1) and (2) are exactly opposite.

Now, according to W. Pauli, L. Landau and L. Posener[3], the first change of susceptibility is given by

$$d\chi_1 = +\frac{2}{9}\frac{CL^{\frac{1}{3}}\alpha_0^{\frac{1}{3}}}{W^{\frac{1}{3}}\rho_0^{\frac{2}{3}}}\left\{-2+\frac{A}{3\alpha_0}\left(\frac{4\pi}{3M}\rho_0\right)^{0\cdot488}\right\}\frac{d\rho}{\rho_0},$$

where $C = 2\cdot21 \times 10^{-14}$, L = Loschmidt's number per mol, W = atomic weight, ρ = density, α = number of free electrons per atom, $A = 2\cdot261 \times 10^{-12}\, Z^{0\cdot513}$, Z = the atomic number and M = mass of the atom.

According to Sommerfeld[4] and T. Hironé[5], the second change of susceptibility is given by

$$d\chi_2 = -\frac{4\cdot13 \times 10^{-7}\, Z^{-\frac{2}{3}}\,\alpha_0 v_0}{a\quad W}\left(\frac{3M}{4\pi}\right)^{\frac{1}{3}}\cdot\rho^{-\frac{1}{3}}\cdot\frac{d\rho}{\rho_0}+$$

$$\left\{2\cdot06\times10^{-7}x_0^2Z^{-\frac{2}{3}}+0\cdot662\times10^{-5}\alpha_0^{-\frac{2}{3}}\right\}\frac{A}{W}\left(\frac{4\pi}{3M}\rho_0\right)^{0\cdot488}\frac{d\rho}{\rho_0};$$

$$\text{where } x=\frac{r}{a},\ a=\frac{0\cdot4676}{Z^{\frac{1}{3}}}\times10^{-8},\ r=\sqrt[3]{\frac{3M}{4\pi\rho}}.$$

Hence, $d\chi = d\chi_1 + d\chi_2$.

ρ, $d\rho$ and α[6] being known from the experimental data, all the quantities found in the expression for $d\chi$ will be known, and $d\chi$, therefore, can be calculated.

The result of the calculation by the above method and also the observed change of magnetic susceptibility for tin, copper, silver and gold are given in the accompanying table:

Phase change	α_0	ρ_0	$\frac{d\rho}{\rho_0}$	$d\chi_1 \times 10^6$	$d\chi_2 \times 10^6$	$d\chi \times 10^6$ (theor.)	$d\chi \times 10^6$ (obs.)
Allotropic change, white tin → grey tin	0·06	7·29	− 0·20	− 0·031	− 0·273	− 0·31	− 0·32
Melting of tin	0·043	7·18	− 0·028	− 0·006	− 0·047	− 0·052	− 0·061
„ „ copper	0·036	8·38	− 0·041	− 0·011	− 0·153	− 0·164	− 0·120
„ „ silver	0·044	9·86	− 0·050	− 0·009	− 0·105	− 0·114	− 0·097
„ „ gold	0·043	18·39	− 0·052	− 0·007	− 0·080	− 0·087	− 0·071

Thus the very interesting phenomenon mentioned above in the case of tin can be explained by our theory. As is seen from the table, the observed change of susceptibility from white tin ($\chi = +0\cdot027 \times 10^{-6}$) to grey tin ($\chi = -0\cdot29 \times 10^{-6}$) is $-0\cdot32 \times 10^{-6}$, while the theoretical value is $-0\cdot31 \times 10^{-6}$; and the observed change in susceptibility of tin during melting from paramagnetic to diamagnetic is $-0\cdot061 \times 10^{-6}$, while the theoretical value is $-0\cdot052 \times 10^{-6}$. A similar comparison between the observed change of the susceptibility during melting and its calculated value in the case of copper, silver and gold shows also good agreement between these two values.

Production of Electron Pairs

DIRAC's theory of electrons gives us the possibility of calculating the production of electronic pairs by collisions between electrons and nuclei. This process may be described as a second order effect of the perturbation of plane electron waves due to the nuclear field, and to the interaction between the incident electron and the electron which originates the pair in the transition from a negative to a positive energy state (rising electron).

If we regard the nuclear field as acting only on the rising electron, and if we assume Møller's[1] primitive electron interaction, we obtain as the cross-section for the production of a pair, of energy between ε and $\varepsilon + d\varepsilon$, by an electron of energy w_0 in field of a nucleus Ze,

$$d\sigma_0 = \frac{56}{9\pi}\alpha^2Z^2\left(\frac{e^2}{mc^2}\right)^2\log\frac{2\varepsilon}{mc^2}\cdot\log\frac{w_0}{\varepsilon}\cdot\frac{d\varepsilon}{\varepsilon}, \quad \ldots \quad (1)$$

if $w_0 \gg \varepsilon \gg mc^2$, in harmony with the results of Landau and Lifshitz[2] and of Williams[3].

Møller's primitive interaction is only available,

however, for first order processes: for second order processes it must be modified by an appropriate generalisation of the Bethe and Fermi method[4]. If we introduce this correction, which is equivalent to computing the reaction of the process on the incident electron, we obtain as cross-section

$$d\sigma_1 = \frac{14}{9\pi}\alpha^2 Z^2 \left(\frac{e^2}{mc^2}\right)^2 \log^2 \frac{2\varepsilon}{mc^2}\frac{d\varepsilon}{\varepsilon} \quad . \quad . \quad . \quad (2)$$

Even this cross-section is incorrect, because it neglects the action of the nuclear field on the incident electron, while on the other hand we may suppose that the excess impulse is given to the nucleus by this electron rather than by the rising one. If we calculate the process only with this last nuclear action, we obtain as cross-section

$$d\sigma_2 = \frac{8}{9\pi}\alpha^2 Z^2 \left(\frac{e^2}{mc^2}\right)^2 \log^2 \frac{2\varepsilon}{mc^2}\frac{d\varepsilon}{\varepsilon} \quad . \quad . \quad . \quad (3)$$

(If we assume Møller's primitive interaction without modifications, $d\sigma_2$ would be small in comparison to $d\sigma_0$ and $d\sigma_1$.)

To obtain the right expression for the cross-section, it suffices to sum $d\sigma_1$ and $d\sigma_2$, because the product of the matrix elements due to the two nuclear actions is antisymmetrical as regards the electron and positron, and vanishes with the integration. We have then

$$d\sigma = \frac{22}{9\pi}\alpha^2 Z^2 \left(\frac{e^2}{mc^2}\right)^2 \log^2 \frac{2\varepsilon}{mc^2}\frac{d\varepsilon}{\varepsilon}, \quad . \quad . \quad . \quad (4)$$

and integrating,

$$\sigma = \frac{22}{27\pi}\alpha^2 Z^2 \left(\frac{e^2}{mc^2}\right)^2 \log^3 \frac{2w_0}{mc^2} \quad . \quad . \quad . \quad . \quad (5)$$

We see then that even in this approximation, we must neither neglect the reaction of the process on the incident electron, nor the interaction between this electron and the nucleus.

A fuller calculation and discussion of this problem will shortly be published.

Registration of the Ionisation Curve of a Single α-Particle

IN a recent letter[1], Dr. Alfvén of Uppsala has described a method for measuring the ionisation along the track of individual α-particles. Some years ago, an almost identical method was developed in this laboratory[2] (Fig. 1) and has been used for the investigation of the α-rays from radium and polonium[3]. The main difference between this method and that developed in Uppsala appears to be that, thanks to the oblique direction of the α-rays to the field, with the former method complications from different saturation are largely eliminated. Also the loss of ions to the grid is avoided by the application of a suitable potential. We have, however, of late abandoned this method for others giving more accurate results; namely, for the counting of α-particles and H-particles the "Doppel Röhrenelektrometer"[4], and for exact measurements of the specific ionisation along individual α-tracks the method recently published by G. Stetter and W. Jentschke[5], also using a twofold registration.

[5] G. Stetter u. W. Jentschke, *Phys. Z.*, **36**, 441; 1935.

I AM sorry that I overlooked the papers cited by Prof. Stetter. In excuse I may state that the first paper is published under the title "Eine neue Methode zur Messung der Ionenbeweglichkeit", the second is unobtainable here, the third is published in a journal not very much read, and the fourth was published after my letter was sent to NATURE.

In any event, I do not agree with Prof. Stetter, that my experiment is a copy of his. The main features of the former are:

(1) The ions move with *constant* velocity to a special chamber where they cause a current which is amplified. In some experiments in 1929 I tried to move the ions by a slow air current, but with bad results. In the experiment described in my letter, it is made with a *homogeneous* electrical field. As the grid and the chamber have the same potential in Prof. Stetter's experiment, the field (deriving from the "Durchgriff" only) is not homogeneous. Then the ions do *not* move with a constant velocity and there is no possibility of constructing the ionisation curve from the current to the amplifier.

(2) The amplifier is constructed in such a way that the *current* to the first grid (not its integral) is registered by the oscillograph. Then the ionisation curve is *directly* registered on the oscillogram. In Prof. Stetter's experiment, the registered curve must be differentiated to give the current to the amplifier. In the registrations he has published it seems to be impossible to differentiate the curve with any degree of accuracy.

As regards complications from different saturation and the loss of ions to the grid, I do not think that these are of much importance in an experiment which in any event gives only an approximate picture of the ionisation curve.

The Fundamental Paradox of the Quantum Theory

THE question of the logical consistency of quantum mechanics has recently been discussed by Prof. G. Temple[1] and by Dr. H. Fröhlich and Dr. E. Guth[2]. Temple arrives at an apparent contradiction, starting from principles which he states to be an essential part of quantum theory. From these principles contradictory results follow, as Temple shows by a perfectly rigorous deduction. (The existence of this deduction seems to have been ignored by Fröhlich and Guth.)

The main assumption used by Temple is that to every function of the classical variables of motion (momentum, co-ordinate, etc.) there corresponds one unambiguously defined operator which may be taken as the representative of this function in quantum mechanics. Although this assumption can be found quite frequently in papers discussing the principles of quantum theory, and even in some text-books, I would like to emphasise that it is not at all necessary and—as one can see from Temple's argument—not even possible in quantum mechanics.

Quantum mechanics requires operators as representatives of physical variables for two purposes: to connect wave functions with experiments, actual or possible, and to calculate the time dependence of the wave function. In order to be able to apply quantum mechanics unambiguously to actual problems, one must, therefore, know (*a*) the operator representing the quantity measured by any given apparatus, and (*b*) the energy operator for any given physical system. Properly speaking, (*a*) is a special case of (*b*), for the properties of a measuring apparatus can always be analysed if its interaction energy with the object in question is known.

If, then, we had an apparatus built in such a way as to measure, say, qp^2q (p denoting the momentum, q the co-ordinate of a particle), this apparatus would be *different* from an apparatus measuring $\frac{1}{2}(p^2q^2 + q^2p^2)$, although in the limiting case of classical mechanics, where quantum effects are negligible, both would measure the same quantity.

Before applying such an apparatus (assuming, for the sake of argument, that it exists although it probably does not) one would have to make sure, either by experimental investigation or by applying quantum mechanics to its working mechanism, which operator actually is to be associated with it. In other words, an apparatus which is quite suitable for measuring a certain quantity in the classical limit may not satisfy our requirements if we rebuild it on a smaller scale, because then quantum effects will have to be taken into consideration.

That one never meets with any difficulty about the order of factors in the usual applications of quantum theory is due to the fact that only very simple operators occur in practice. The most typical of them is the energy of an electron in a field of force, $p^2/2m + V(q)$ (m = mass, V = potential energy). One generally assumes that the function in this exact form, without quantum corrections, has to be taken as the energy operator of a particle the energy of which would be given by the same expression in classical mechanics. This assumption seems very *natural*, but it cannot be *proved* on mere theoretical grounds. All one can say is that this expression is the *most plausible* amongst a variety of different expressions, which all become equal in the classical limit but differ by terms like, for example, $pV - Vp = (h/2\pi i)\text{grad } V$ (h = Planck's constant). It is for the experiment to show that the most plausible choice corresponds to reality and that such correction terms are absent.

That the absence of these correction terms cannot be inferred from mere theoretical considerations is proved by the fact that when relativity and spin corrections are taken into account, such terms actually *do occur*.

Uncertainty Principle and the Zero-Point Energy of the Harmonic Oscillator

ACCORDING to quantum mechanics, an oscillator possesses a definite zero-point energy of vibration, and an attempt has been made to express this result *directly* in terms of some general principle. It has been found that the result may be deduced from the uncertainty principle, in view of the particular relation between position, momentum and energy in a simple harmonic field.

In a state of zero energy the vibrating particle would be at rest at the centre of the field, and its position and momentum would both be known accurately. But this would contradict the uncertainty principle, and the state is therefore not possible. The value of the minimum energy may be calculated from the uncertainty relation $\Delta p\, \Delta q \geqslant h/2\pi$. The linear harmonic oscillator is defined by the energy equation

$$W = \tfrac{1}{2}\mu\omega^2q^2 + \tfrac{1}{2}p^2/\mu = \text{constant}.$$

If we interpret

amplitude of q = Δq = uncertainty in position,
amplitude of p = Δp = uncertainty in momentum,

then $W = \frac{1}{2}\mu\omega^2(\Delta q)^2 = \frac{1}{2}(\Delta p)^2/\mu$,
giving $\mu\omega\, \Delta q = \pm\, \Delta p$.

For real Δp the positive sign must be taken, and from the uncertainty relation, $(\Delta p)^2 \geqslant h\mu\omega/2\pi$, and therefore $W \geqslant \frac{1}{2}h\omega/2\pi$. Taking the equality sign for the least value of the energy, it follows that the zero-point energy is $\frac{1}{2}h\omega/2\pi$.

The Problem of a Plant Virus Infection

IN a recent publication[1] an account was given of a new virus disease which occurred spontaneously in tobacco plants growing under insect-proof conditions in sterilised soil and sand. It was shown that the cowpea (*Vigna sinensis*), on account of its extreme sensitivity to the virus, was a valuable experimental plant. In continuing studies upon this disease, some observations have been made which will be of interest to virus workers.

It has been found by inoculation tests that a high percentage of healthy tobacco plants of the variety White Burley carry the virus in the roots. These plants are absolutely normal in appearance and under the present conditions of light and temperature in

the glasshouses remain normal until mature. Careful tests have failed to demonstrate the presence of the virus in the stems and leaves of young tobacco plants which are carrying the virus in the roots. The virus has, however, been isolated on one or two occasions from the stems of old, apparently normal, tobacco plants.

It therefore appears that a large proportion of tobacco plants of the White Burley variety normally carry a potential virus disease within them, and it is thus possible to inoculate a perfectly healthy plant from its own roots and to produce thereby severe, though localised, virus symptoms. Visible disease symptoms develop naturally in tobacco seedlings in the glasshouses from November until April, but have not been observed during the summer.

Further, and this is the most interesting point, there is a good deal of evidence that the same young tobacco plants which, by available inoculation methods, have been shown to be virus-free, yet contain the virus in the roots in quite large quantities some five or six weeks later.

The following experiment illustrates this. Seed from a White Burley tobacco plant grown in the insect-proof glasshouse was sown in sterilised sand in a 'cellophane' cage in the glasshouse. From the resulting seedlings a number of small plants were chosen and all the roots cut off except that one root was left on each plant. The roots of each plant, thus removed, were ground up and the resulting paste inoculated separately to three or four cowpeas. The tobacco plants were then repotted in sterilised soil and allowed to grow on; from this number twenty-four plants, the roots of which had given no reaction on the cowpeas, were selected for a second test. This was made, again to cowpeas, five weeks after the first test. The plants were by this time about eight inches across with a well-developed root system and showed no unusual symptoms. Of these twenty-four plants, on the second test, the roots of only five were found to be virus-free. The roots of the others gave a virus reaction ranging from twenty-five lesions, on five cowpeas out of five inoculated, down to a single virus lesion.

In considering these results, certain other facts should be borne in mind; exhaustive tests make the possibility of outside infection by seed-, soil-, or water-transmission unlikely, though seed transmission in some form cannot be definitely excluded. The virus is not insect borne. Further, it should be emphasised that natural infections of the virus have not occurred on any plant other than the tobacco, *Nicotiana tabacum*, and, occasionally, on *Nicotiana glutinosa*. Plants like cowpea, *Datura* and tomato have never once in five years become naturally infected in the glasshouse, although growing alongside virus-containing tobacco plants. Yet these species, especially the cowpea, are very susceptible to artificial inoculation with the virus.

Other properties of the virus which may have a bearing on the problem are its lack of resistance—it only remains viable in extracted sap for about 20 days—its low dilution end-point of 1 : 10,000 and its inability to withstand desiccation. The virus is of very small size; the average particle diameter is only 20–30 mμ as measured by the Elford process of ultra-filtration. Finally, there is the tendency of the virus to remain localised in the host whether the infection is natural or artificial and whatever the species of host plant. This fact also militates against the probability of seed transmission of the virus.

There seem to be three possible explanations of this problem. First, it may be assumed that the virus is present all the time in the stem, but present either in a non-virulent form which requires to gain virulence by concentration in particular cells of the roots or else in a dilution too great to give a positive reaction on inoculation. This theory, of course, involves seed transmission of the virus in undetectable form or quantity. The second possible explanation is that the virus is arising spontaneously within the plant. The third possibility, and perhaps the least likely, is the existence of a mode of virus transmission quite unknown to plant virus workers.

Non-identity of Vitamin D_2 (Irradiated Ergosterol, Calciferol) and the Natural Vitamin D from Cod Liver Oil

As will be known from numerous papers, these two forms of vitamin D have different biological actions. In children and in chicks, one rat unit of the natural vitamin D of cod liver oil is about a hundred times as potent against rickets as one rat unit of irradiated ergosterol. Hence Steenbock[1] has concluded that the two substances are not identical. Chemical and physical proofs of the difference between the two substances have been advanced by Ender[2], who showed that vitamin D_2 differed from the natural vitamin D in its reaction with phthalic anhydride, its ultra-violet spectrum and its rotation of polarised light. As basic material, Ender used the liver fat of the tunny (*Thunnus Thynnus*) on the assumption that the vitamin D in various fishes is the same. However, Bills, Massengale and Imboden[3] have found that one rat unit of Blue-fin tunny liver oil in chicks has only 15 per cent of the antirachitic effect of one rat unit of cod liver oil, whence they conclude that the two forms of vitamin D are different.

We have therefore made comparisons between the vitamin D from cod liver oil and irradiated ergosterol (D_2). The former was concentrated by the methods described by Rygh[4] and Weidemann[5]. The vitamin A was eliminated by the method of Dalmer, v. Werder and Moll[6]. 200 kgm. of cod liver oil yielded 8 gm. of a concentrate containing 3×10^6 international units vitamin D per gram. The original oil contained 150 international D-units per gram; the vitamin D had thus been concentrated about 20,000 times. The results of the comparisons are stated below, where also the results of Ender with tunny liver oil are quoted:

	D_2	D-concentrate of cod liver oil	D-concentrate of tunny liver oil
Ultra-violet spectrum	Max. 265 mμ	No max.	No max.
$[\alpha]_d$ in alcoholic solution	+ 103°	260–270 mμ ± 0°	260–270 mμ ± 0°
Per cent esterification with phthalic anhydride and pyridine after 10 days	about 30	100	100
Effect of maleic anhydride	none	none	none
Monohydric alcohol	+	+	+

The data are not sufficient to determine whether

vitamin D from cod liver oil and from tunny liver oil are different or identical. But they show that both these forms of vitamin D are different from irradiated ergosterol.

Abnormal Magnetic Behaviour of Treated Cobalt Wire

THE magnetisation curve was determined for a length of cobalt wire of 0·194 in. diameter in the condition as received and the result is shown by the curve *A* in Fig. 1. In this figure the values of $4\pi I$, that is, the 'metallic magnetic density', are plotted against the magnetising force as abscissæ. The maximum permeability of the wire in this condition was found to be 100, the corresponding value of *H* being about 35 oersteds.

The wire was then heated by passing an alternating current through it in an atmosphere of hydrogen, and the current was of sufficient strength to raise the temperature of the wire quickly to about 1,200° C., this temperature being maintained for a few seconds. The magnetisation curve was obtained after the wire had cooled down, and the result is shown by curve *B* in Fig. 1. The maximum permeability in this case was found to be 370, the corresponding value of *H* being 7 oersteds. So far as I am aware, this is the highest value for the permeability of cobalt at room temperature which has yet been recorded.

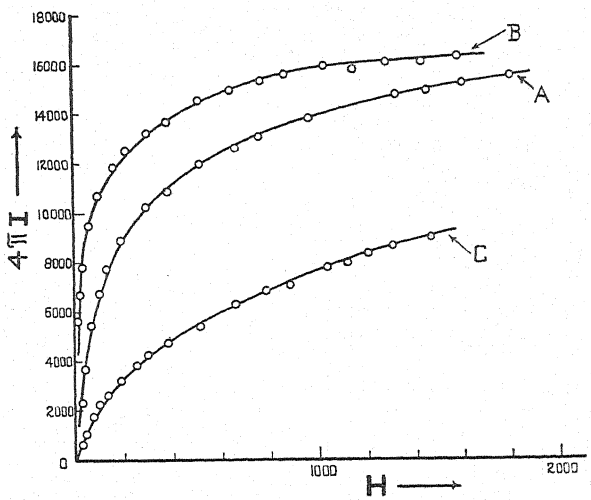

FIG. 1.

The wire was next placed in an atmosphere of hydrogen and an alternating current of frequency 50 was passed through it for several hours, the current being such that the temperature was maintained at about 1,200° C. After the wire had cooled down, the magnetisation curve was again obtained and is shown by curve *C* in Fig. 1. The striking features of this curve are that the saturation metallic density would appear to be only about 60 per cent of that of the normal cobalt, whilst the maximum permeability is now only 30.

The treatment is being continued to find out to what magnetic condition the wire will eventually settle down, and similar investigations are being made for iron and nickel wires.

Unit of Force in the M.K.S. System

THE decision of the International Electrotechnical Commission to recommend the use of the M.K.S. system of electrical, mechanical and magnetic units, as reported in NATURE of July 6, may have far-reaching consequences, for experience has shown that a unit in daily use by engineers soon becomes a familiar quantity, and as such is preferred for quantitative work even by the pure physicist. The statistical examination of the question by G. A. Campbell[1] shows this very clearly: the practical units, volt, ohm, ampere, coulomb, etc., are used by the pure physicist far more than the corresponding C.G.S.M. or C.G.S.E. units. Since the M.K.S. system also possesses advantages for mathematical work, it is at least possible that it may ultimately become universally used.

This possibility will be very considerably increased if all the units have convenient names. In the M.K.S. system, the unit of energy is the joule, and the unit of power is the watt, but no name has yet been assigned to the unit of force, the force which, acting on a mass of 1 kilogram, gives it an acceleration of 1 metre per sec. per sec. G. Giorgi[2] has provisionally used the word 'vis' but the 's' ending makes the use of the plural awkward. Moreover, the derivation of the word is not in conformity with the derivation of the names of the closely related units of energy and power, which have been called after famous men of science. We venture to suggest that 'newton' would be more appropriate. The name of Newton is universally associated with the idea of impressed force, the word complies with the suggestion of G. A. Campbell[1] that the name chosen should have no more than two syllables, and as Newton's name cannot but occur again and again throughout the teaching of even the most elementary mechanics, pronunciation should present no difficulty in other countries.

We understand that the unit of magnetic flux has been called the 'weber'. If the ampere-turn be adopted as the unit of magnetomotive force, which means that the system would be rationalised, then no additional names for units would be necessary. This is certainly not the strongest of arguments for rationalisation, but we would emphasise the importance of easily remembered names with no risk of confusion, and would deprecate the use of a unit for *H* which would require yet another new name. Although a definite ruling on the use of the C.G.S.M. units, the gilbert, gauss, oersted and maxwell has been given, there is still confusion between them in published papers.

Upper Carboniferous Fossils in America and Europe

THE interesting note by Prof. A. E. Trueman in NATURE of June 29, p. 1074, recalls to mind some studies of Upper Carboniferous cockroaches, which I made a number of years ago. The results are fully set forth in *Annals and Magazine of Natural History*, April 1927, but it is now pertinent to quote (p. 393):

"The typical Mylacridæ (using this expression to exclude the series related to *Hemimylacris*) abounded in America throughout Allegheny time, yet never, so far as we know, reached Europe. This suggests that the Blattid faunæ of the two sides of the world were not intermingled to any extent during that period, and makes it rather improbable that various Archimylacrid genera crossed over, though they may have done so prior to the rise of the Mylacridæ."

It is possible that land connexions northward were utilised by the plants, but were not usually available to the tropical or subtropical cockroaches. It is also possible that various types of plants did not appear simultaneously on both sides of the world, but developed first on one side and eventually reached the other. But all these matters require more detailed discussion, which is impossible here.

Methylene Blue as a Stain for Mucus

IN spite of a somewhat adverse criticism, and a statement apparently to the contrary[1], methylene blue is one of the best and easiest stains for mucus. According to Bolles Lee, "Microtomist's Vademecum", p. 497 (ninth edition), *Methylene blue is particularly useful from its power of bringing out the merest traces of mucin*, while the following very simple experiment illustrates this.

A few specimens of the common snail (*Helix aspersa*) are collected and placed on small pieces of glass. They soon crawl off leaving a trace of mucus. If the pieces of glass are placed, without further treatment, in a 0·01 per cent aqueous solution of methylene blue the mucus stains a deep blue within two minutes.

Chirocephalus lives apparently quite comfortably in this solution for an hour, and long before that time patches of mucus or a mucus-like secretion appear deeply stained within the median groove.

Points from Foregoing Letters

MRS. BARLOW quotes from Darwin's unpublished manuscripts, dealing with the fauna of Galapagos Islands, to show that so early as 1837 Darwin had begun to doubt the stability of species.

On removal of the xylan from manilla hemp cellulose fibres, X-ray photographs have been obtained which indicate a more perfect state of crystallisation, and are similar to photographs of fibres of low xylan content. W. T. Astbury, Dr. R. D. Preston and Dr. A. G. Norman state that this is compatible with the view that the association of the xylan with cellulose is a mixed crystallisation.

Dr. W. H. George submits a photomicrograph of an etched surface of a crystal of copper (grown by the Bridgman method). Its appearance, similar to that of polycrystalline metals, suggests that the crystal has broken down into a large number of small ones; X-ray photographs show that their orientation has remain unchanged.

New measurements, in vacuum, of the changes in magnetic susceptibility of tin, copper, silver and gold, during allotropic transformation or melting, have been made by Prof. K. Honda and Y. Shimizu. To check Honda's theory, they compared the experimental values with those obtained by adding the change in paramagnetic susceptibility calculated according to the equation of Pauli, Landau and Posener, to the change in diamagnetic susceptibility from the formula of Sommerfeld and Hirone.

Prof. G. Racah discusses the cross-section for the production of pairs of positive and negative electrons by collisions between electrons and nuclei. He submits several approximate formulæ and concludes that both the reaction of the process on the incident electron and the interaction between this electron and the nucleus must be taken into consideration.

Many papers discussing the principles of quantum theory have assumed that to every function of the classical variables there corresponds one unambiguously defined quantum operator. This assumption, writes Dr. R. Peierls, is not necessary in quantum theory, and consequently the paradox pointed out by Prof. Temple can be obviated.

From the uncertainty principle, which states that the position and momentum of a particle cannot both be known accurately at a given time, R. A. Newing calculates the zero-point energy of the harmonic oscillator to be equal to $\frac{1}{2}h\omega/2\pi$.

Dr. Kenneth Smith describes the occurrence of a virus in the roots of a high proportion of normal tobacco plants. The virus appears in the plants under conditions which are usually considered virus-proof. Three possible explanations of the problem are discussed.

The ultra-violet absorption, optical rotation and certain chemical reactions of synthetic vitamin D are found by Dr. O. Rygh, of the State Vitamin Institute, Oslo, to differ from those of vitamin D prepared from cod liver and tunny liver oil. The author concludes that synthetic vitamin D (obtained by irradiating ergosterol) is chemically different from the natural product, which may explain the reported discrepancy in their potency as a cure for rickets in children.

A cobalt wire was heated for some hours to about 1,200° C. in an atmosphere of hydrogen by an alternating current at frequency 50. After the wire had cooled down, Dr. T. F. Wall finds that the saturation value of the intensity of magnetisation was only about 60 per cent of that for the normal cobalt.

The word 'newton' rather than 'vis' is suggested by Dr. L. Hartshorn and P. Vigoureux as a name for the unit of force in the M.K.S. system, that is, for the force which, acting upon a mass of one kilogram, gives it an acceleration of one metre per sec. per sec.

Research Items

Culture Areas in Nigeria

MR. WILFRID D. HAMBLY, as leader of the Frederick H. Rawson-Field Museum Ethnological Expedition to West Africa, 1929–30, has made a cultural survey of Nigeria based upon a synthesis of the evidence of physical characters, language, social and material culture, also taking into account geographical factors (Field Museum of Natural History Pub. 346, Anthrop. Ser., 21, No. 3). Broadly, the country falls into three regions—southern, northern and an intervening plateau area. South of lat. 9° N., negro somatic traits prevail; north of that line modifying physical characters are to be noted, and the farther north the more strongly are negro traits overlaid until on the border of the Sahara the type is definitely non-negro. The intruding elements are Hamitic and Semitic. In linguistics the two main divisions are Bantu-speaking and Sudanic-speaking, the main languages north of lat. 9° N. being Hamitic and Semitic, supplemented by Sudanic negro languages. Culturally, there is a type of culture which is fundamental to the whole of Nigeria, though the negro elements are more deeply entrenched south of the line of 9° N. Allowing for local differentiation there is, in fact, in West Africa a predominating uniformity in the pattern of forest negro culture through Liberia, the Ivory Coast, Ashanti, Dahomey, Nigeria, Cameroon and the Congo Basin, into the land occupied by the Ovimbundu of Angola. Among such elements are, for example, skill in ironwork, wood and ivory carving, pottery made by coiling and punching, bark cloth, hoe cultivation by women, and in the social life similarly certain fundamental elements are to be noted. Foreign elements superimposed on the negro culture are Hamitic, Semitic, Mediterranean and European. These are found more especially in the north and are associated with occupations centring in the keeping of camels, horses and cattle. In the plateau area, on the other hand, are cultural pockets, which preserve modes of life that are probably of early negro character.

Marriage among Aimol Kukis, Assam

IN the course of a study of the social organisation of the Aimol Kukis of Assam, by Mr. J. K. Bose (*J. Depart. Letters*, Calcutta Univ., 25), it is indicated how changes in social conditions have affected and modified the regulation of marriage. The Aimol Kukis were at one time organised in a dual division, in which it was the rule that members of the superior moiety should marry in the inferior moiety. Nowadays, one of the clans in the inferior moiety is practically extinct, and the people of the superior moiety, now greatly in the majority, experience great difficulty in finding a suitable mate. Although they are strictly exogamous, they are thus forced to abandon the practice of marrying in the opposite moiety, and must wed within their own moiety, still, however, strictly avoiding marriage within the clan or its subdivisions. Another modification, which is being introduced, by outside contacts, is that of payment for the bride by money instead of the three years service by which formerly the bridegroom earned from the bride's family the right to return with her to his own village. This form of marriage by service was that which was most generally recognised, and even now purchase is only beginning to be introduced among the more well-to-do. Four other forms of marriage are admitted: elopement, when the parents do not like the marriage upon which the parties concerned have agreed between themselves; capture, which takes place when a young man, having served for a period of, say, a year, is driven out by his future father-in-law for no serious cause; marriage of a widow, usually by a younger brother of the husband, no ceremony taking place or price being paid; and mutual settlement between the parties to live together without any marriage ceremony, when a fine is imposed by the girl's father for the loss of his daughter.

Survival in Tree-Swallows

THE very great efficiency of nesting in the tree-swallow of the United States of America (*Iridoprocne bicolor*), under not quite natural conditions, is illustrated by the observations of Winton Weydemeyer (*Condor*, 37, 216, July 1935). For eight seasons he has kept records of the nesting activities of tree-swallows making use of bird-houses erected by him, and occupied yearly by eight to sixteen pairs. Full records of 60 nests, 52 of which were first brood nests, 8 second broods, show that the former contained 324 eggs, the latter 39. Of these there hatched 319 and 39; six nestlings of the latter died, and 12 of the former were taken by a sparrow-hawk; but of the total number of nests, in 44 out of 52, and 6 out of 8 their total clutch was raised without loss. Including all accidentals, of failure to hatch and so on, the efficiency of the nests studied is represented by 94·7 per cent of survival in the case of first broods and 84·5 per cent in the case of second broods.

A Warty Growth on the Head of Land-Snails

I. TAKI (*J. Sci. Hiroshima Univ.*, 3, 1935) directs attention to a peculiar warty structure on the head, between the two posterior tentacles, of adult snails belonging to the family Cepolidæ, and to a concavity, containing three to twenty tubercles, in a corresponding position in the family Pleurodontidæ. The head-wart consists of a number of modified dermal tubercles, in two genera in a single sinuous row, but in all others forming a group of various sizes and shapes. The head-wart has a particularly thick epithelium and its interior is occupied by connective tissue in which are fibrils, chromatophores and blood-lacunæ. The rudiment of the head-wart is visible in the early stages of development of the snail; the wart attains its full size by rapid growth at the time of sexual maturity. In the breeding season the head-wart in certain genera forms a conspicuous hemispherical protrusion; external stimuli cause its contraction. The protrusion of the wart is effected by increase of pressure of the blood, which takes place before copulation. From the position of the head-wart, its rapid growth at sexual maturity and its swelling, it is inferred that the wart has some bearing on the sexual activity of the snail, though it is not clear how it functions.

Host Selection by Insect Parasites

G. SALT (*Proc. Roy. Soc.*, B, **117**, 805; 1935) has investigated the process of selection of host-species by the ovipositing females of a small chalcid parasitoid, *Trichogramma evanescens*. Ovipositing females were observed to examine, select and attack, besides a number of true hosts (such as the egg of the Angoumois grain-moth, *Sitotroga cerealella*) from which their progeny successfully emerged, several unsuitable hosts in which their progeny were unable to develop, and a variety of false hosts, such as particles of sand and globules of mercury, in which they were not able even to lay their eggs. Two strains of *Trichogramma* reared exclusively on *Sitotroga cerealella* and the Mediterranean flour-moth, *Ephestia kuehniella*, respectively for 63 and 43 generations, developed no dependence on or even preference for their respective hosts. Both strains preferred eggs of *Ephestia*, but an analysis of the preference showed that it was not a specific preference for *Ephestia* but a preference for it simply as the larger host. When two different kinds of hosts were simultaneously exposed to *Trichogramma* the latter showed a preference for the larger of the two, even though the preferred host was unsuitable for the development of its progeny or was a false host in which the parasite could not even lay its eggs. Size appears to be the principal criterion used by ovipositing females of *Trichogramma* in the selection of their hosts.

Vessel-less Dicotyledons

THE anatomy of the four homoxylous genera of Angiosperms, *Drimys*, *Zygogynum*, *Tetracentron* and *Trochodendron*, has been re-examined by K. M. Gupta, University of Lucknow (*J. Indian Bot. Soc.*, 13, No. 1, 1934). He points out that they may be sharply divided into two groups: (1) *Drimys* and *Zygogynum*, with several species distributed in Australian and South American regions; and (2) *Trochodendron* and *Tetracentron*, monotypic genera confined to Japan and China respectively. In the *Drimys* group the growth rings are absent or faintly marked, the rays scarcely or not at all enlarged at the junction of the growth rings, the ray cells uniformly pitted on radial and tangential walls and the pitting on the tracheids of the spring wood is of the multiseriate type. In the *Trochodendron* group, growth rings are well marked and the rays enlarged at the junction of the growth rings, and the pitting of the tracheids of the spring wood is scalariform. He also points out that all four genera can be distinguished by the shape of the ray cells as seen in tangential longitudinal sections. The anatomical data are briefly used in a discussion of the vexed problem of the origin of the Angiosperms but, apart from emphasising the importance of the Magnoliales in connexion with this problem, the theoretical significance of these vessel-less dicotyledons still remains obscure.

English and Canadian Tomato Virus Diseases

THE presence in England of Dr. G. H. Berkeley, a Canadian plant pathologist, has been put to considerable profit in the elucidation of difficulties of virus disease nomenclature. A co-operative study has been made with the Rothamsted and Cheshunt Experimental Stations ("A Comparison of English and Canadian Tomato Virus Diseases" by Drs. G. C. Ainsworth, G. H. Berkeley and J. Caldwell, *Ann. App. Biol.*, **21**, No. 4, 566–580, Nov. 1934). Seven distinct viruses have been studied, namely: tomato mosaic, yellow mosaic, single-virus streak, mixed-virus streak, ring mosaic, tobacco virus No. 9, and spotted wilt. The last-named disease apparently does not occur in Canada, whilst ring mosaic and the No. 9 virus have not yet been recorded in England. Mixed-virus streak is not common in England, but the other viruses mentioned above are relatively common in both countries.

Virus Diseases of Ornamental Plants

DR. KENNETH SMITH has published a paper on "Some Diseases of Ornamental Plants caused by the Virus of Tomato Spotted Wilt" (*J. Roy. Hort. Soc.*, 60, Part 7, July 1935). The disease on the tomato causes the leaves to curl downwards and inwards, whilst bronze-coloured spots, with an almost metallic lustre, appear upon the leaflets. Many other garden plants are attacked, including the Iceland poppy, various stocks, tropæolum, begonia, several plants belonging to the Compositæ, campanula, calceolaria, gloxinia, arum, hippeastrum, and more than a dozen species of Solanaceæ. Symptoms vary on each of these hosts. *Thrips tabaci* is the only insect concerned in distribution of the malady, and destruction of this pest, along with the removal of infected plants, are the chief methods of control advocated in the paper.

Molasses and Nitrogen Fixation in Soil

IN two recent publications, N. R. Dhar and S. K. Mukerji (*Proc. Acad. Sci. U.P., India*, **4**, 175; 1934; 330; 1935) have shown that when cane sugar is added to sterilised or unsterilised soil and exposed to light and air, there is an appreciable increase in the ammoniacal nitrogen content; with unsterilised soils the ammoniacal nitrogen is nine times greater than that originally present in the soil. With sterilised soil it is about three times as great. The amount of ammonia in presence of light is always greater than in the dark. By the addition of molasses to soils which have been properly aerated, the ammoniacal nitrogen may become three times as great as that originally present in the soil. When the aeration of the soil is less, the increase of ammonia is less and the soil becomes acidic. It appears that in tropical countries in ordinary soils, the fixation of atmospheric nitrogen by the addition of energy-rich compounds is partly bacterial and partly photochemical. The oxidation of the energy-rich organic compounds by air either by chemical induction, light absorption or bacterial action causes the fixation of the atmospheric nitrogen in the soil. These researches may be of considerable practical importance, because the molasses available in the sugar factories in India are wasted at the present time.

The "Amal" Bunsen Burner

THIS new type of laboratory burner, which was briefly described in NATURE of December 1, 1934, has been improved by the inclusion of a pressure-damping device which, by proportioning the flow of gas to the size of the jet orifice, enables the flame to be turned down still lower than was previously possible; and also by the provision of a set of detachable heads. These provide a horizontal rose flame, horizontal and vertical batswing flames, the fully aerated bunsen flame and, for the smaller burner only (the "Amal minor"), a dental head that gives a rotatable flame projecting at a convenient angle so

that molten material cannot drop into the burner and choke the jet, this flame being convertible at will into a luminous flame by putting on a small tip. The head giving the vertical batswing flame contains a small hole providing a tiny hot flame for 'spot' heating. The Amal burner possesses all the advantages and more of the Meker and Teclu burners, and also all those of the ordinary 'bunsen' except the control of air-supply. A further adaptation is the "Amal" petrol-gas burner, which works well on the gases from Silverlite and Aerogen plants. It resembles the town's gas burner, but has only one hole for admitting secondary air, and this is regulated by a spring band clip.

Mandelic Acid: a Urinary Antiseptic

INFECTIONS of the urinary tract are troublesome and serious complaints that frequently fail to yield to ordinary treatment. A ketogenic diet has been found to be curative, and A. T. Fuller (*Lancet*, **1**, 1933 855;) showed that under it β-hydroxybutyric acid is formed, appears in the urine, and is the actual bactericidal agent. This acid cannot, however, be given orally, as it becomes oxidised in the body before excretion. A ketogenic diet, moreover, requires careful and institutional supervision, and is also not tolerated by all patients. Seeking for a substitute, M. L. Rosenheim (*Lancet*, **1**, 1935) 1032; tested numerous keto- and hydroxy-acids allied to β-hydroxybutyric acid, and found that mandelic acid best realises the conditions necessary, for it is excreted unchanged, is non-toxic in therapeutic doses, and is bactericidal in an acid urine to *Bacillus coli* and other organisms that may infect the urinary tract. In order to ensure an acid condition of the urine, ammonium chloride is given with it. Mandelic acid is a white crystalline powder, readily soluble in water, and is now being manufactured by Messrs. Boots Pure Drug Co., Station Road, Nottingham, from whom particulars may be obtained.

Preparation of Silanes

ALTHOUGH monosilane, SiH_4, was prepared by Buff and Wöhler in 1857 and its physical and chemical properties have been exhaustively investigated by Stock and co-workers since 1916, the method of preparation has been unsatisfactory. Stock allowed magnesium silicide, prepared by the reduction of silica with magnesium at high temperatures, to drop into aqueous hydrochloric acid, when a mixture of gases was evolved containing 40 per cent SiH_4, 30 per cent Si_2H_6 (disilane), 15 per cent Si_3H_8, 10 per cent Si_4H_{10} and 7 per cent higher compounds. Only 23 per cent of the silicon in the magnesium silicide appeared as gaseous hydrides. In 1934, Kraus and Carney reported a very convenient and efficient method of preparation of hydrides of germanium, giving yields of more than 60 per cent by dropping ammonium bromide into a suspension of magnesium germanide in liquid ammonia, the ammonium salt behaving as an acid in somewhat the same manner as hydrochloric acid in aqueous solution. W. C. Johnson and S. Isenberg (*J. Amer. Chem. Soc.*, **57**, 1349; 1935) now find that this method may be used to obtain high yields of silanes, varying from 70 to 80 per cent. Magnesium silicide was prepared by heating finely divided silicon with magnesium filings at 475°–1,000° in an atmosphere of hydrogen. The fine blue powder so obtained was dropped into a solution of ammonium bromide in liquid ammonia and the gas evolved passed through slightly acidified water and then dried with phosphorus pentoxide and condensed in liquid nitrogen. The product was then fractionally distilled. It was found that pyrex stopcocks lubricated with vacuum grease were satisfactory, and that it was not necessary to use mercury valves in manipulating the gases. The physical properties of the mono- and disilanes agreed with those found by Stock and co-workers. It was found that 50 per cent ferrosilicon did not react with ammonium bromide in liquid ammonia unless first heated with magnesium filings, when an unusually high yield of disilane was obtained.

Crane Hooks, Links, etc.

AMONG the papers selected by the Council of the Institution of Mechanical Engineers for publication in *Proceedings* is a contribution by Messrs. Gough, Cox and Sopwith, on the "Design of Crane Hooks and other Components of Lifting Gear". These components consist in the main of curved beams, made of ductile material, of which the radii of curvature are, usually, relatively small. They are distinguished by very complex stress distributions, and have been the subject of various theories from which and from much accumulated practical experience their makers have evolved methods of design giving safe but not, in the opinion of the authors, economical results in practice. The National Physical Laboratory and the British Standards Institution have been engaged in research, standardisation and specification in connexion with this group of lifting gear components with the results reported in the paper now issued. The effect of the curvature of the centre line is first discussed, then that of local yielding, and it is shown that, when this occurs, the removal of the load results in a reversal of stress in the locality of the set. The calculated elastic stresses thus become, in service, ranges of stress as the component is loaded and unloaded, and the material is called upon to withstand the calculated stress as a range which should not exceed the numerical sum of the yield stresses in tension and compression. The method of calculating the bending moment in rings, links, etc., is shown, with comparisons between approximate and exact methods, and general formulæ are obtained for egg links, studded links and eye-bolts, typical examples from recent British Standard Specifications being worked out.

Spectrum of a Hot Carbon Star

THE spectrum of the irregular variable star *R* Coronae Borealis has been studied in detail by L. Berman (*Astrophys. J.*, **81**, 369) in three-prism spectrograms taken at the Lick Observatory. The wave-lengths of about 650 lines have been measured over the region 4300–4900 A., and the absolute numbers of atoms engaged in their production deduced from observed line intensities and theoretical intensity ratios of supermultiplets. Carbon is found to be abnormally abundant, and constitutes 69 per cent of the atmosphere of this star, the remainder of which is composed of 27 per cent hydrogen, 4 per cent metals (chiefly magnesium and iron), and less than 0·3 per cent nitrogen. The effective temperature of the star is computed to be 5300° K.; the colour temperature in the blue is about 1,000° higher, and in the red about 1,000° higher still, though the last result may be vitiated by the difficulty of defining the true continuous background in this region.

Imperial Botanical Conference

THE Imperial Botanical Conference which met on August 27–30 in the rooms of the Linnean Society, Burlington House, London, is the third of a series which dates from the years immediately following the War. At that time, the International Botanical Congresses, initiated in pre-War years, which were due to be held at five-yearly intervals, were in abeyance. Thanks to the efforts of a committee of British botanists a conference of Empire botanists, on a scale fairly comparable to that of an International Congress, was arranged for the year 1924, and took place in London. Quite apart from its value to scientific botany generally and to the advancement of botanical study within the Empire in particular, that Conference undoubtedly acted as a stimulus to the resumption of normal friendly relations between European botanists which had been sadly interrupted.

Now that the International Congresses are again established—first at Ithaca, N.Y., in 1926, then at Cambridge in 1930, and in the present year at Amsterdam—the need for Imperial Conferences has to some extent disappeared, at least from the point of view of general botanical science. It was felt, however, that such conferences would still serve a useful purpose in relation to problems of special Imperial interest, to the organisation of research, and not least to the formation of contacts between widely scattered groups of workers. A small committee was therefore kept in being. A short conference, of a purely formal nature, was held in 1930, and now the third of the series has taken place. The subjects for discussion were limited to those of general economic interest to the Empire, and were in the main suggested by botanists overseas.

In his address of welcome to members, the president, Sir Arthur Hill, emphasised the ever-increasing importance of botanical research in the development of Imperial agricultural resources, not merely with regard to crops which figure in export trade, but also to the food plants of the native and his animals. The study of native crops with the view of obtaining maximum yields under the various local conditions is a work of the greatest national importance which calls for the continued co-operation of botanical and agricultural workers at home and overseas.

Pasture Research

Prof. R. G. Stapledon, in introducing a series of papers on "Pasture Research Within the Empire", dealt with the importance of 'strain' in pasture plants. Studies at Aberystwyth have abundantly shown that grassland plants are no exception to the general rule that botanical species contain within their ambit a more or less indefinite number of strains or varieties. Between the strains of a particular grass or clover there might be a greater difference in agricultural value, for example, permanence in the pasture, feeding value, economic return, etc.—than there is between desirable and undesirable species. These strains or groups of strains have been evolved on a geographical basis, partly in response to climatic and soil conditions, but probably to a large extent as a result of long-continued farming practices. The work of the plant breeder is in the first place to discover which are the most desirable of these local groups for special purposes, and then to ensure that in commercial exploitation any tendency to deterioration is effectively checked. The sowing out of pure strains is not desirable inasmuch as a certain degree of variability gives some insurance against the vagaries of climate and of farming practice. The maintenance of pure strains, with subsequent judicious blending, is a splendid ideal which is very difficult to achieve and is in fact not necessary. The difficulty of maintaining the quality of a certain group of strains ('ecogroup') is not so great as is sometimes imagined and can be overcome for all practical purposes if the work is carried out in a suitable locality and on a large enough scale. The essential point is to safeguard the quality of the original stock, and this can only be done under the direct control of the plant breeding station.

The problems involved in the improvement of pastures in the Dominions were outlined by Dr. I. B. Pole-Evans for the Union of South Africa, and by Prof. G. W. Scarth and Mr. H. J. Whyte for eastern Canada. Dr. Pole-Evans described the natural pasture areas of the Union, and in this connexion exhibited a comprehensive series of coloured plates illustrative of the South African flora. Much damage to natural pastures has already been done by indiscriminate grazing, by burning and by other malpractices. This he ascribed to a general absence of fundamental knowledge relating to the problems of veld management. He reviewed the research work which has been carried out in the Union up to the present and stated that a national research programme has now been organised which will deal in particular with problems relating to the general decline in the carrying capacity of the veld due to faulty grazing methods. This programme will also aim at the building up of an organised animal industry based on the development of the natural pasture potentialities of the country.

In presenting the Canadian problems, Prof. Scarth pointed out that the natural pastures of eastern Canada are at the moment the most important in the Dominion, inasmuch as they carry more than half of the total livestock. A striking feature is that though these pastures have never been ploughed, the significant part of the herbage consists of introduced European plants which have in course of time colonised these areas. The pastures are generally poor and the trend is towards further deterioration. A very comprehensive programme of research, organised both on a Federal and on a State basis, is now being carried out, involving ecological mapping in association with soil surveys, manurial trials in relation to quantity of herbage and to stock rearing or milk production, biochemical studies of pasture plants, etc. The main result so far established is that the pastures as a rule respond markedly to the addition of phosphatic fertilisers, the poor type of *Agrostis* sward being replaced in time by the better grasses with clovers. The formulation of recommendations applicable to the different soils and climates will only be possible after vigorous research over many years. An ecological study of certain

pastures of eastern Canada was presented by Mr. H. J. Whyte and served to illustrate the poor quality of many of these and the need for improvement.

Certain detailed aspects of pasture research in England were described by Mr. G. E. Blackman and by Mr. Martin Jones of the Jealotts Hill Research Station of Imperial Chemical Industries, Ltd. Mr. Blackman showed that under spring conditions, nitrogenous manuring stimulates growth within a certain temperature range only. During midseason, water supply rather than nitrogen is the controlling factor. The effect of light on the growth of pasture plants is complex, varying with the species, with the available nitrogen supply and even with the form in which the latter is added.

Mr. Martin Jones dealt with the competition to which the constituents of grassland are subjected by neighbouring plants and showed how differences in habit or rate of growth lead to the dominance of certain forms or the suppression of others. Grazing by animals is of the greatest importance in this connexion, the effects on the development of any particular constituent varying according to the intensity of grazing at any given period. The correct management of grazing is therefore essential for the maintenance of any particular type of pasture.

Tropical Forests

In a session devoted to "Succession of Tropical Forest Types" Dr. Burtt Davy dealt with the evolution of tropical African forest types and pointed to the presence of a considerable percentage of Indo-Malayan forms in West Africa though they are no longer to be found in East Africa. He attributed this peculiar distribution to elevation of the land surface, subsequent to migration, with resulting lowering of temperature and desiccation of considerable areas of low country. It was therefore suggested that low-level, broad-leaf tropical rain-forest was at one time more widespread in East Africa than it is now. The presence of a small but significant palæoarctic element extending from Abyssinia as far south as temperate South Africa indicates relatively modern immigration along the temperate zone corridor formed by the high eastern mountain chain.

The distribution of forest types in Nyasaland was briefly described by Mr. P. Topham. The range of elevation within the region extends from 200 ft. to 10,000 ft. and at least nine groups of forest types are to be noted. The biotic factors of greatest importance in relation to distribution are local history, bush fires, cultural methods, fallow periods, grazing and soil rejuvenation by termites. In the absence of long-term fire protection experiments and of fuller local records, the ecological succession of the different types is largely speculative.

The distribution of various Nigerian forest types in relation to temperature, rainfall and elevation was described by Mr. W. D. MacGregor, and particular stress was laid on the succession from the open park-land to the moist deciduous type of forest. Experiments have shown that over considerable areas such a succession takes place with fair rapidity provided there is a nucleus of deciduous forest sufficiently near to supply an abundance of wind-borne seed and provided the area is protected from farming and, in its earlier phases, from grass fires. The importance of enlarging the area of deciduous forest as a check to advancing desiccation from the Sahara was emphasised.

Mr. P. Richards gave a comparative account of three areas of tropical rain forest situated in British Guiana, Sarawak and Nigeria respectively. Each area was studied intensively rather than extensively, and the data were collected so far as possible in a quantitative form. The structure was studied by means of profile diagrams based on measurements of all the trees on clear-felled plots, and the floristic composition was at the same time determined. The structure is fairly similar in all three localities. An interesting point is the close analogy of the forests on white sand in Sarawak and British Guiana, suggesting that there may be parallel edaphic variations from the climax in different regions of the tropics.

An ecological investigation of peculiar interest was described by Mr. C. G. Trapnell in relation to the application of ecological methods to the study of native agriculture in Northern Rhodesia. Various native tribes have discovered—some more exactly than others—the association of certain wild plants with soils of a certain type and are able to fix on the location and decide on the nature of their cultivated crops in accordance with such observations. Efforts to advance the prosperity of the country should be directed towards building on the foundations already laid by the native himself, rather than to hazardous introductions or innovations.

Fruit Storage

The enormous amount of research, much of it emanating from Empire sources, which has in recent years been directed to problems of fruit storage and transport, made it peculiarly suitable that a session of the Conference should be devoted to that subject. The fact that, as one speaker pointed out, imports of Empire fruit into the British market have increased six-fold in the last twenty-five years and now constitute nearly half of the total import shows how research and the practical application of it are proceeding hand in hand with the advancement of Imperial trade.

Of the eight papers presented, five came from overseas contributors and the remainder from workers of the Food Investigation Board. The problems involved are of extraordinary complexity, involving as they do not merely the factors which immediately affect storage of fruit—for example, temperature and humidity of the store, mode of packing, state of maturity of fruit when put in the store, etc.—but a multitude of others which come into play while the fruit is still on the tree. Such are the effects of soil, of climate, of rootstock and so forth on the keeping quality of the fruit. The problems are in the main similar whatever the fruit or the country of origin, though the relative importance of the different factors may vary from one problem to another. For these reasons no summary which would even indicate details will be attempted here.

Dr. C. Wardlaw and Mr. R. Leonard discussed the problems of the storage of tropical fruit. Investigations at the Imperial College of Tropical Agriculture range from empirical testing of the storage behaviour of various tropical fruits—banana, lime, grape fruit, avocado pear, etc.—to fundamental studies of the gaseous exchange occurring during growth and ripening. Canadian researches, summarised by Dr. H. T. Güssow, covered the whole field of the storage of apples. Mr. H. Turner of the New Zealand Fruit Board dealt chiefly with systems of refrigeration and

methods of stacking fruit in the holds of ships. Mr. N. E. Holmes, in connexion with the transport of Australian citrus fruit, discussed fungal spoilage and loss of flavour in relation to age of the fruit, and the value of various methods as tests of the state of maturity, while Mr. D. J. Dreyer described experiments relating to mechanical damage to South African pears. With reference to the gas storage method, which has been rapidly taken up by some English growers of apples in the last few years, Dr. C. West advised a certain amount of caution, as much research work still remains to be done before the method is placed on a sound basis. Finally, papers of a fundamental nature were read by Dr. A. S. Horne and by Mr. R. Gane, the former discussing the results of a quantitative study of the resistance of apples to fungal invasion and the latter dealing with some interesting effects of ethylene gas on the respiration and maturing of banana fruit.

In the final session, Prof. E. E. Cheesman directed attention to the pressing need for greater facilities within the Empire for the collection and classification of crop varieties and related species. The menace of Panama disease and of witch-broom disease to banana and cacao cultivation respectively makes it imperative that wholehearted attempts should be made to discover or to breed suitable varieties of the crop plants resistant to these diseases. The work is seriously handicapped at the moment by the lack of adequate facilities.

An interesting feature of the Conference was a series of exhibits comprising, in addition to the illustrations of South African plants already mentioned, a collection of types of cultivated *Sorghum* and of cowpea (*Vigna* sp.) prepared by the staff of the Royal Botanic Gardens, Kew, and an exhibit illustrating Linnæus's development as a botanist arranged by the Librarian of the Linnean Society.

Conference of Empire Meteorologists

TWENTY-FIVE Dominions and Colonies were represented at the third Conference of Empire Meteorologists which was in session at the Meteorological Office, South Kensington, on August 12–21. Six years have elapsed since the previous conference and there have been important changes during that period, both in the organisation of colonial meteorological services and in the demands made upon them for data, either for home consumption or for international dissemination. There were two main reasons for calling the conference, first to give the directors of services an opportunity of discussing their problems before proceeding to the International Conference of Directors to be held at Warsaw this month; secondly, to discuss the meteorological arrangements necessary to meet the Government's requirements in connexion with the Empire air-mail scheme.

At the same time, the meetings provided an opportunity for the exchange of views on many other questions of a general character. In meteorology, problems of co-ordination are not less important than purely technical problems. It is, therefore, very necessary that the administrators of meteorological services should meet from time to time to discuss these matters. Within the Empire we have a wide diversity, not only in climate but also in the administrative arrangements for handling meteorological data. A meeting of Empire meteorologists thus provides a means for considering problems from every angle, and has a special value for that reason.

At the opening meeting on August 12, the delegates were welcomed by Sir Henry Lyons, vice-chairman of the Meteorological Committee. Mr. J. Patterson, director of the Canadian Meteorological Service, was elected president of the Conference. At the first business meeting, the Government's policy in regard to the Empire air-mail scheme was outlined. This scheme involves both day and night flying, and adequate meteorological services must be a fundamental part of the necessary ground organisation. Linked up with the question of organisation are such technical matters as the making of synoptic charts on a uniform plan, the coding of reports from land stations and ships and the choice of hours of observation. Air-mail pilots are familiar nowadays with synoptic charts, and it is important that they should be able to consult up-to-date charts at their ports of call. It is also important that a symbol they see on a chart in one country should have the same meaning as a similar symbol on a chart they see in another country. The delegates will have to consider the international aspect of this matter of symbols at Warsaw, and the discussion in London proved very useful.

Questions connected with aviation and with synoptic meteorology occupied the first few meetings. These were followed by discussions on meteorology for the Army and for the Navy, instruments, upper-air observations, marine meteorology, geophysics, climatology and agriculture, and seasonal forecasting. The use of upper-air data has assumed increased importance with the advent of air-mass analysis for the purpose of synoptic diagnosis. In many colonies there are special difficulties, however, in the way of obtaining the data. One difficulty is that of procuring hydrogen for the inflation of pilot balloons, and it was of interest to learn how the difficulty is being met in Canada by the use of a portable electrolytic generator, and in East Africa by an ingenious chemical generator, the essential part of which has been adapted from a commercial pressure-cooker.

In connexion with geophysics, the Conference passed a resolution recommending the establishment of a station at Chesterfield Inlet, Hudson's Bay, Canada. This station would be in near proximity to the North Magnetic Pole and its situation would also be very favourable for auroral studies. The conference also recommended the establishment of a station at Tristan da Cunha, observations from which, situated as it is about midway between the Cape of Good Hope and South America, would be of great value.

The discussions on climatology and agriculture began on August 19. Perhaps the most interesting subject in these categories was that of the broadcasting of climatological data. Students of world climatology have previously been handicapped

seriously by the difficulty of obtaining current climatological data. The monthly summaries issued by the various services are often published many months in arrear, and it has thus been impossible to put together an up-to-date picture of the climatological conditions all over the land areas of the globe. Lieut.-Colonel E. Gold gave an outline of a scheme for the broadcasting of brief data from selected stations in each country on the fifteenth of the month following that to which the data refer. This scheme will come before the international conference at Warsaw; its successful realisation would be an advantage not only to climatologists but also to business men who require recent information in regard to the general weather conditions in distant lands.

The subject of seasonal forecasting gave rise to an interesting discussion. Everyone of course recognises the great advantages that would ensue if some reliable method could be evolved for forecasting the general character of the weather some weeks or months in advance. The existing methods were brought under review, but it can scarcely be claimed that we are within sight of a solution. An elaborate preliminary study of the main causes of variation may, as in the case of the monsoon rainfall of India, result in the derivation of an equation from which a forecast can be made with a certain degree of success. The general view, however, was that none of the methods hitherto explored had given results good enough to justify the inauguration of an official service of long-range forecasts. E. G. B.

Educational Topics and Events

GLASGOW.—The King has been pleased, on the recommendation of the Secretary of State for Scotland, to approve the appointment of Mr. Duncan MacCallum Blair, professor of anatomy and Dean of the Medical Faculty, King's College, University of London, to be regius professor of anatomy in succession to Prof. T. H. Bryce, whose resignation takes effect on September 30.

COLLEGE library administration carried to a high pitch of activity is exemplified in Columbia, Missouri, where librarians, spurning the role of mere custodians of books, make it their business to become acquainted with and contribute to class-room instruction and make systematic provision for acquainting lecturers with the library's resources with reference to current work. They visit classes, participate in faculty meetings, hold instructional conferences with students and conduct introductory orientation classes. Collections of books are disposed where they are most easily accessible to students both in common-rooms, in class-rooms, in laboratories and in hostels. Conversely, the instructional staff, besides encouraging students to make the most of the library's resources, act as assistant librarians and give regular instruction in the technique of reading, especially the timed reading exercise followed by a comprehension test. In fact, reading is recognised as the student's chief tool, and the college holds itself responsible for seeing that every student becomes highly skilled in the use of it. The head librarian is at the same time dean of instruction and his aim is to make the library the "heart of the college". The above facts are gleaned from correspondence in *School and Society* of May 18.

Science News a Century Ago

Consumption in Man and Animals

IN a long review of "A Treatise on Pulmonary Consumption" by Dr. James Clark, M.D., F.R.S., the *Athenaeum* of September 5, 1835, said: "The Chapter on the Statistical History of Consumption contains many curious facts, and is accompanied by several valuable tables affording much matter of interesting reflection to the political philosopher. It appears that more than one-fourth of those who die from birth to puberty are affected with tuberculous disease; that the greatest number of deaths from consumption occur between the age of twenty and thirty . . . the mortality being probably at its maximum at thirty and gradually diminishing from that age. . . . The chapter on the disease in animals affords much interesting information. . . . In the gardens of the Zoological Society in Regent's Park Mr. Owen has found the disease in the tiger, the Persian lynx, the paradoxure gennet, the civet cat, the Indian ichneumon, the brown coati mondi, the Nepâl bear of the Himalayas, the American tapir, the American elk, in various monkeys, in the Eskimaux dog and in the lungs of the Python tigris".

The Zoological Society

AT a meeting of the Zoological Society held on September 8, 1835, Thomas Bell being in the chair, "a marmazet was presented from Mr. Moore of Rio Janeiro, the first that has ever been seen alive in this country. This, the most diminutive species of the monkey tribe, is about the size of a small rat, and even when full grown can be put into a half-pint tumbler. The greatest singularity is its large bushy tail, in which it completely envelopes itself when it retires to repose, to screen itself from the cold. The countenance of this species is that of an old man; and the one presented to the Zoological Society is said to bear an exact resemblance to that of a celebrated French diplomatist". (*The Times*, September 14, 1835.)

Capt. Back's return from the Arctic

ON September 10, 1835, *The Times* announced the arrival in Liverpool of Capt. George Back on his return from his journey in search of Capt. John Ross, and the following day quoted the following passages regarding Back's expedition from the Montreal papers: "During the first winter the expedition had to endure great privations, owing to the scarcity of food and the severity of the weather. Captain Back is the first European who has visited the Great Fish River and examined its course to the Polar Seas. Its very existence was doubted by many geographers. It is said to be large, but dangerous navigation; greatly impeded by ice; it falls into the Polar Sea. Further than this, we only know that the party of intrepid travellers had to encounter every obstacle to which Polar navigation is liable, and we are led to believe that immense masses of ice, with severe weather finally arrested their progress. Captain Back will, we believe, have much interesting information to communicate respecting his observations on the Aurora, the changes on the needle as he drew northward, etc. The extreme cold he experienced, we learn, was 70 degrees below zero. The expedition returned to Fort Reliance which Captain

Back left on the 20th March 1835, and travelled on snow-shoes to Chippewayan; from this station he departed on the 28th of May and arrived at Lachine on the 6th of August." Back, who was born in 1796, was knighted in 1839, and was made an admiral in 1857. He died on June 23, 1878.

Progress of the London and Greenwich Railway

THE *Mechanics' Magazine* of September 12, 1835, said: "The London and Greenwich Railway viaduct is now fast approaching completion, and presents a very imposing appearance. It forms a highly interesting object from the summit of Nunhead Hill, at the back of Peckham, from which the whole range of arches, seen in nearly its entire length, appears like the 'counterfeit presentment' of a Roman aqueduct. Nunhead Hill is decidedly the best point from which to obtain a general view of this magnificent work, which there forms a part of the foreground to an exquisite and comprehensive panorama of the metropolis, in its whole enormous length from Chelsea to Greenwich, with all its 'domes and spires and pinnacles', amongst which those of Westminster Abbey and St. Paul's are of course the most conspicuous."

Societies and Academies

PARIS

Academy of Sciences, July 16 (*C.R.*, **201**, 181–244). JEAN LOUIS DESTOUCHES: Definition of the stability of propositions. ROBERT FORTET: Probabilities '*en chaine*'. ANTOINE APPERT: Normal measures in separated spaces. A. RAUCH: The extension of a theorem of Lindelöf and Phragmén. DAVID BELORIZKY: The nebular spectrum of Nova Herculis. MATÉI MARINESCO: The use of low-frequency reaction in triode valves. GEORGES VAUDET and RENÉ SERVANT: The spectra of exploded wires in the extreme ultra-violet and the Schumann region. A fine wire, exploded by an electric current, forms a very intense light source, as although the time of exposure was of the order of 20 microseconds, good photographs were obtained with a grating. The lines were spark lines. MICHEL DUFFIEUX: The influence of the chemical medium on the bands of the second positive group of N_2. HUA-CHIH CHENG and JEAN LECOMTE: Some remarks on the vibration frequencies of chlorine derivatives. Discussion of Raman and infra-red spectra. PAUL SOLEILLET and SERGE NIKITINE: Comparison of the polarisation of the light emitted by resonance in an atomic jet and in the non-directed vapour. ANDRÉ KLING and ARNOLD LASSIEUR: The electrical conductivity of water. The electrical conductivity of water does not appear to be constant, and the determination of small quantities of carbon dioxide in solution by measuring the electrical conductivity is impossible. GEORGES COLANGE: Research on the optimum lighting of photographs and engravings. WITOLD BRONIEWSKI and W. PIETREK: The structure of the nickel-cobalt alloys. Curves are given showing the variation of physical properties with the composition. There is no evidence of the existence of a definite compound of nickel and cobalt in these alloys. ETIENNE CANALS, PIERRE PEYROT and ROGER NOËL: The fluorescence of some pure substances. ARTHUR AKERMANN: The adsorption by active carbon of dilute organic vapours and their desorption by pure air. LÉON MOREAU, GEORGES CHAUDRON and ALBERT PORTEVIN: A new method of extracting the gases contained in metals. The metal forms the cathode in an evacuated discharge tube, connected with a Langmuir pump. The extraction is made at the ordinary temperature. Aluminium, after removing gas by the ordinary method (fusion in a vacuum) gave additional gases by the new method, sixteen times the original amount. FÉLIX FRANÇOIS: The system, antimony iodide – ammonium iodide – water. VICTOR LIVOVSCHI: On 4.7-dimethyloxindol. GEORGES DUPONT and RAYMOND DULOU: The pyrolysis of pinene. A new type of monocyclic terpenes, the pyronenes. The new hydrocarbons are characterised mainly by their Raman spectra. FRANÇOIS KRAUT: The origin of the breccias of Chassenon (Charente). These breccias are sedimentary formations, in which occur remains of pumice and scoria, probably from an ancient volcano nearby, in addition to debris of the crystalline substratum. CONSTANTIN PIERRE NICOLESCO: Hydrological researches in the chalk of the Paris basin. AUGUSTE CHEVALIER and RAYMOND FURON: Some Tertiary and Quaternary deposits of the islands of Cape Verde. HENRI BESAIRIE and VICTOR HOURCQ: The stratigraphy of the upper Jurassic of Madagascar. A. GUILLERD and E. BEDON: An experiment with fluorescein on the losses of the Ognon, above Lure (Haute-Saone). This river disappears into permeable strata. Experiments with the dye showed that one third of the missing water emerged in the springs of La Font (Lure), and La Noireau (Magny). JAMES ALLOITEAU: The necessity of studying sections for the determination of the Polypiers of the Cretaceous. RENÉ SOUÈGES: The embryogeny of the Verbenaceæ. The development of the embryo in *Verbena officinalis*. ROBERT LÉVY and RENÉ AUDUBERT: The emission of radiation by the eggs of *Discoglossus* in the course of development. MAURICE LEMOIGNE and ROBERT DESVEAUX: The formation of hydroxylamine in cultures of *Sterigmatocystis nigra* in a medium enriched with ammonium nitrate. GASTON RAMON and ANDRÉ STAUB: Vaccination for anthrax.

LENINGRAD

Academy of Sciences (*C.R.*, **2**, Nos. 5–6, 1935). M. G. KREIN: A special class of differential operators. G. V. PFEIFFER: An integrating factor of a system of symbolic equations, equivalent to a system of linear equations in Jacobians, which satisfies the generalised conditions of Hamburger. G. B. GUREVICH: Classification of trivectors of the eighth degree. P. P. LUKIN: Dependence of internal forces on the main virial of the outer forces. N. V. ADAMOV: Geometrical meaning of the stability condition given by Liapunoff. V. EFREMOVICH and M. KREINES: Topology of surfaces of second order. TH. JUDALEVICH: Optical phenomena connected with the change in size of the spherical particles of a disturbed medium. P. A. WALTHER and S. D. PONOMAREV: Investigation of hydraulic grids. N. N. GUSEV and M. B. NEUMANN: Rate of combustion of pentane mixtures. L. J. KURTZ: Kinetics of the formation of anode films on metals (1). Protective films of silver chloride and bromide on silver. N. J. DEMJANOV and N. I. PUTOCHIN: Action of nitrous acid on triptophane. V. O. LUKASHEVICH and M. A. VOROSHILOVA: Reduction of nitrogen compounds by

iron shavings. M. K. DJAKOVA, A. V. LOZOVOJ and S. I. CHERTKOVA: An investigation of the chemical composition, properties and methods of treatment of primary tars of Cheliabinsk brown coal. G. N. MASLIANSKIJ and M. S. NEMCOV: The poisoning of molybdenum-zinc catalyst. E. A. RAZBAUM and A. N. FIL'POV: Chemical composition of lawrovite. A. E. CHODJKOV: Tertiary deposits and the boundary of glaciation in the eastern part of the Narym region, Western Siberia. P. P. LAZAREV and L. N. FORMOZOVA: Influence of illumination on some processes in plants (2). Influence of illumination on the quantity of water and of organic substances in plants. R. I. SEREBROVSKAJA and N. I. SHAPIRO: Frequency of mutations induced by X-rays in the autosomes of mature and immature germ-cells of *Drosophila melanogaster* males. S. G. LEVIT: Sex-linked genes in man (and their relation to the problem of dominance). V. N. NIKITIN: Physiology of milk secretion.

VIENNA

Academy of Sciences, June 27. MARGARETE HOFFER: Evaporation experiments in vacuum with polonium, radium D and radium E. With electrodes containing RaD, RaE and Po, the last evaporates at lower temperatures than RaE or RaD, the differences being about 250° and 300° C. respectively. With aged electrodes, the values are higher for all three elements, but the order remains the same. ELISABETH RONA and MARGARETE HOFFER: Evaporation of polonium in oxygen and nitrogen. An apparatus is described which allows of the preparation, evaporation and measurement of the polonium in a definite gas-space, without contact with the external air. The evaporation occurs at a lower temperature in nitrogen than in oxygen. MARIETTA BLAU and HERTHA WAMBACHER: Sensitiveness of desensitised photographic films in dependence on atmospheric oxygen and on the concentration of the desensitiser. The results obtained agree best with the oxidation theory of the desensitisation process. JOSEF SCHINTLMEISTER and ERNST FÖYN: Disintegrability of the elements from argon to manganese by polonium α-rays. Only potassium gave an observable, though very small, yield of H-rays, other elements giving not more than about 0·2 H-rays per 10^6 polonium α-rays. ERNST BEUTEL and ARTUR KUTZELNIGG: Behaviour of cellulose towards liquid chlorine, iodine, and iodine monochloride. ERICH TSCHERMAK-SEYSENEGG: Genetics of dimorphism and occurrence of homostyly in primulas. FRITZ LIEBEN and BELLA BAUMINGER: The system sugar – amino acid – yeast. LEONORE BRECHER: Pre-induced alterations in the light-reaction threshold for the coloration of *Dixippus morosus*, Br. et Redt. FRANZ MAUSER: Synchronous metamorphosis of transplanted fore-legs in *Dixippus morosus*, Br. et Redt. ATMA MALABOTTI: Histological investigation of the stick grasshopper with transplanted head. HANS PRZIBRAM: (1) Heat-sum and temperature quotient. Results obtained in the investigation of egg development, larval growth and chrysalis duration are given. (2) Quantum growth with vertebrates. (3) Transference of the metabolic level of temperature-modified rats to their progeny. KONSTANTIN TZONIS: Direct current narcosis in insects. JUSTUS ROSENHAGEN: The path of the Prambachkirchen meteorite. ARMIN DADIEU and WOLF ENGLER: Raman spectrum of $CDCl_3$. For ordinary chloroform, the spectrum consists of the six frequencies (intensities in brackets), 263(4), 369(4), 671(5), 765(3*b*), 1219(2), 3022(4). For $CDCl_3$, these become 265(4), 367(4), 657(5), 740(3*b*), 916(2), 2254(4). The line 2254 cm.$^{-1}$ corresponds with the C–D valency vibration, and 916 cm.$^{-1}$ also depends essentially on the C–D linking. ARMIN DADIEU and HANS KOPPER: Raman spectra of DBr and C_2H_5SD. RUDOLF LEUTNER: Velocity of hydrolysis of cyclic acetals (2).

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, **21**, 301–412, June 15). CHARLES H. MCBURNEY, WALTER B. BOLLEN and ROGER J. WILLIAMS: Pantothenic acid and the nodule bacteria – legume symbiosis. The stimulating effect of innoculating alfalfa and other legumes with appropriate bacteria has hitherto been explained on the theory that the bacteria fix nitrogen. Small quantities of pantothenic acid, which can be synthesised by *Rhizobium meliloti*, exert a marked stimulating effect on the growth of alfalfa. Culture experiments suggest that pantothenic acid is not the deciding factor in the nitrogen fixation process, but rather it plays an important part in the carbohydrate anabolism of the plant. FRANCIS G. BENEDICT and ERNEST G. RITZMAN: Lability of the basal metabolism of the dairy cow. Feeding experiments on five Holstein (*c.* 600 kgm.) and four Jersey (*c.* 300 kgm.) cows, ranging in age from 3 years to 15 years and extending over periods from two months to three and a half years, show a significant higher level (ranges of 10–90 per cent for individuals) during the pasture season (June) and a tendency for a minimum during March. There was also frequently a profound change in the metabolic level within a period of two months (ranges of 30–85 per cent for individuals). Rubner's concept, formulated about fifty years ago, that all resting warm-blooded animals give off heat in direct proportion to their surface areas, and at a constant rate, irrespective of species, of 1,000 cal. per sq. m. of body surface per 24 hours, now requires modification. L. D. LEET: The Provincetown, Massachusetts, earthquake of April 23, 1935, and data for investigating New England's seismicity. A very slight earthquake was felt on this date along the tip of Cape Cod. It was recorded at Harvard, Mass., with a Benioff seismograph. This instrument has been calibrated by recording dynamite blasts in quarries, and it was therefore possible to fix the focus at 117·5 km. from Harvard. More such instruments, which are capable of giving useful records of such slight local earthquakes, are required. ROBERT A. MILLIKAN and H. VICTOR NEHER: Equatorial longitude effects on cosmic rays. A progress report. Shielded and open electroscopes taken on voyages round the world show a sudden dip in causing the equatorial belt—varying from 8 to 12 per cent on different sides of the globe. A similar survey at high altitude, at present incomplete, shows an exponential rise in ionisation with height. These results indicate a dissymmetrical distribution in outer space of the earth's magnetic field with respect to a line passing through the centre of the earth. J. A. STRATTON: Spheroidal functions of the second kind. RICHARD C. TOLMAN: Thermal equilibrium in a general gravitational field. A theoretical discussion. W. W. HANSEN: On the expansion of Green's function. The discussion is confined to scalar equations of mathematical physics. FRANCIS B. SUMNER and DENIS L. FOX: Studies of carotenoid pigments in fishes. (3) The effects of ingested carotenoids upon the xanthophyll content of *Fundulus parvipinnis*. Batches of the Pacific

killifish fed on the chopped flesh and skin of the garibaldi, a brilliant orange-red fish containing much xanthophyll, showed a substantial increase in the concentration and absolute amount of xanthophyll in their tissues. Other batches fed on chopped white meat of the California 'halibut', which contains practically no xanthophyll, neither lost nor added to their stock of xanthophyll. Still other batches fed on beach worms, which are rich in carotene but have no xanthophyll, showed an increase in xanthophyll content. Hence these fish, while unable to produce xanthophyll on a diet free from carotenoids, can apparently convert carotene into xanthophyll, contrary to the prevalent belief that animals must ingest such substances directly or indirectly from plants. A. H. WRIGHT: Some rare amphibians and reptiles of the United States. F. B. SUMNER: Studies of protective colour change. (3) Experiments with fishes both as predators and prey. The predators used were blue-green sunfish, and *Gambusia* adapted to light and dark backgrounds formed the prey. The results confirmed the earlier experiments in which penguins were the predators; that is, light-adapted fish were more readily caught in a dark tank and vice versa. Fish which were immobilised by drugs were also caught more quickly. Conspicuousness, rather than availability, determines survival, and total quiescence is a definite handicap when the predators are also fish. S. BOCHNER: Summation of multiple Fourier series by spherical means. MAX ZORN: The automorphisms of Cayley's non-associative algebra. GEORG AUMANN: On a topological characterisation of compact convex point sets. MARSTON MORSE: Generalised concavity theorems. S. LEFSCHETZ: A theorem of extremals (2). J. H. C. WHITEHEAD: A certain region in Euclidian 3-space. J. VON NEUMANN: On normal operators. A. D. BERGNER and A. F. BLAKESLEE: Chromosomes ends in *Datura discolor*. CURT STERN: The effect of yellow-scute gene deficiency on somatic cells of *Drosophila*. Female cells homozygous for this deficiency are rarely viable. CLYDE E. KEELER: Headdot: an incompletely recessive white spotting character of the house mouse. G. W. BEADLE and A. H. STURTEVANT: X-Chromosome inversions and meiosis in *Drosophila melanogaster*. A general theory of the behaviour of inversions, supported by genetic evidence. HELEN DEAN KING and W. E. CASTLE: Linkage studies of the rat (*Rattus norvegicus*). Breeding tests show that, in the eleven genes which have been identified, two linkage systems occur. E. LUCILE SMITH: X-Ray and abnormalities: increased abnormality of segments in *Drosophila* due to X-raying of gametes. Irradiation of virgin females led to a number of individuals in the first generation having irregular abdomens, increase of irradiation producing larger numbers of abnormal individuals. The effect was not inherited. The suggestion that the effect is due to changes produced in the cytoplasm of the eggs seems to be confirmed by the appearance of few abnormal individuals on irradiation of males, the gametes of which carry little cytoplasm. HENRY FAIRFIELD OSBORN: The ancestral tree of the Proboscidea: discovery, evolution, migration and migration over a 50,000,000 year period. An advance account of a forthcoming monograph on the Proboscidea, with a discussion of the bearing of this work and of Prof. Osborn's corresponding work on the Titanotheres on the mechanism of the evolution of species.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Sunday, September 8

BRITISH MUSEUM (Natural History), at 3 and 4.30.—Miss M. R. J. Edwards: "Pioneers".*

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (NORWICH MEETING)

Monday, September 9

At 10 a.m.—Sir Arthur Smith Woodward: "Recent Progress in the Study of Early Man" (Presidential Address to Section H).

Prof. P. T. Herring: "The Pituitary Body and the Diencephalon" (Presidential Address to Section I).

At 12.—Mr. F. T. Brooks: "Some Aspects of Plant Pathology" (Presidential Address to Section K).

At 3 p.m.—Exhibition of Prof. J. S. Huxley's film "The Private Life of the Gannets" (in the Stuart Hall).

At 9 p.m.—Exhibition of educational films by courtesy of the British Gaumont Instructional Films.

Tuesday, September 10

At 8.15 p.m.—Dr. C. S. Myers: "The Help of Psychology in the Choice of a Career" (Evening Discourse in the Agricultural Hall Assembly Room).

INSTITUTE OF METALS, September 9–12. Annual Autumn Meeting to be held in Armstrong College, Newcastle-upon-Tyne.

September 9.—Dr. H. W. Brownsdon: "Metal Melting—Its Effect on Quality" (Fourteenth Autumn Lecture).

Social Science

THE question of the utilisation of science, raised in a discussion at the recent conference on academic freedom at Oxford, acquires the greater interest through both the recent meeting at Norwich of the British Association and also the way in which political affairs have directed attention to the necessity for considering how science can be used for human welfare. From whatever point of view we regard the dispute between Italy and Abyssinia, or the measures for defence against air raids now being initiated by the British Government, the question as to the misdirection of scientific knowledge cannot be evaded. Similarly, this year's programme for the meeting of the British Association has shown that in many ways the isolation of the scientific worker is breaking down and to an increasing extent he is considering the relation between his work and the society in which he finds himself.

As examples, one need only refer to the symposium on the State control of agriculture arranged by Section M (Agriculture), the discussions on the universities and business and on the future trend of scientific management in Great Britain before the Department of Industrial Co-operation (Section F—Economics), the presidential address to Section L (Educational Science) on education and freedom, part of which appears in this issue of NATURE (p. 416), the symposium on the herring problem arranged by Section D (Zoology). Discussions on the chemotherapy of malaria before Section B (Chemistry), on sugar beet problems before Section M (Agriculture), the place of psychology in the training and work of teachers before Sections J and L (Psychology and Education), the application of science to the control of road traffic before Sections G and J (Engineering and Psychology) or on the economic aspects of diet before Sections F and I (Economics and Physiology) further demonstrate over how wide a front this gathering of scientific workers considered the way in which the application of scientific knowledge can assist in the solution of social and industrial and economic problems.

Discussions of this type have for several years past been a regular feature of the meetings of the British Association, particularly discussions in which two or more sections have been associated in the joint consideration of a particular problem. The growing consciousness on the part of the scientific worker that the extent and direction of scientific work itself is influenced by the social and economic conditions under which he works, no less than the examples afforded of the disappearance of academic freedom in Europe, have quickened the interest of scientific workers in such discussions generally. Even those engaged in the most academic or theoretical investigations to-day cannot be indifferent to conditions around them, on which they depend both for the continuance of support and for freedom of investigation.

The very frailty of civilisation may demand certain limitations on the freedom of investigation possessed by the man of science, however different the purpose and form of such limitations may be as compared with the restrictions imposed in such countries as Germany and Italy. With the very continuance of civilisation itself in doubt, something in the nature of a mobilisation of scientific effort in its support becomes an urgent need. In a state of emergency the limited resources of scientific effort must be utilised where they can supply the greatest safeguard to humanity, whether in respect of supplying the knowledge and technique for the control of the forces already released by applied science, or for the development of a whole

new field of economy and technique for the distribution and enjoyment of the wider resources these forces when wisely used have made possible.

From this point of view, the right of society in a time of emergency to prescribe the directions in which scientific effort shall first be made can scarcely be challenged. Nor is there involved thereby the threat to creative thought which is involved in the prescriptions which we have witnessed of late on the Continent. We are, however, immediately confronted with a problem of co-ordination which is already suggested by such a programme as that of the British Association.

Discussions such as those we have indicated are commonly regarded as contributions to the development of social science. Granted that they represent contributions to our body of organised knowledge bearing on the problems which confront an organised society, how far do they contribute to the solution of problems as visualised by those who are seeking to attack such problems systematically by scientific methods? Can such haphazard discussions lead to the evolution of either policy or technique permitting of the solution of social problems in anything like the way in which problems of physical science are solved?

These questions and the underlying one of the evolution of sociology into a true science have recently been raised by Prof. Julian Huxley in a thoughtful article in the *Fortnightly Review*. The practice of using the term science both in the sense of an organised body of knowledge, as well as in the sense of knowledge and ideas amassed by true scientific methods, tends to much confused thought on sociology and on other subjects described by Prof. W. McDougall as social sciences. Admittedly sociology at the present time is merely a body of more or less organised knowledge, only a fraction of which has been amassed by methods which can be called scientific.

Its position in fact is very similar to that of history, and while on broad grounds Prof. Huxley may be right in objecting that history cannot be classed as a science, to push that objection too far is to be unjust to many investigators whose scientific study of historical method is yielding results of real value for the interpretation of social, political and economic situations, and may provide the basis upon which a true science may yet be built. In just the same way the transformation of sociology into a true science of society may ultimately be effected. Indeed, the scientific study of history may prove a fruitful source of accurate social knowledge.

Prof. Huxley, however, is not content merely to direct attention to the existing confusion of thought on social problems. He indicates the main requirements if social knowledge is to develop into a true science in the way that natural science began to emerge from a mere body of organised knowledge at the beginning of the seventeenth century. In the first place, he reiterates Prof. McDougall's plea for an adequate supply of workers of high standard. This is a first essential for the scientific study of social problems and at once presupposes first the provision of adequate facilities for the training of such workers and the existence of employment for such social workers when trained.

Given a supply of investigators of the requisite quality, the question of social experiments and their control at once looms large. Without experiment, social science can scarcely develop. At present the failure to isolate experiments and difficulties in securing such isolation are almost as great an obstacle to the accumulation of scientific knowledge as the prejudices which often influence the interpretation of their results. Despite the many new departures in economic and social practice which we have witnessed even in the last five years, it is almost impossible to draw sound and valid conclusions owing to the absence of control or the existence of vitiating factors.

The gradual evolution of an appropriate technique and the steady accumulation of social knowledge by scientific methods will go far to establish a definite science of society. Even then, however, such a science must differ somewhat from the physical sciences. In the main the physical sciences represent an approach to truth. In any social science it is the other aspect of science, which the physical researcher is prone to neglect, that is most significant—science as a means of control. Scientific workers must at least give a lead to the administrator and politician in such matters as a first step towards social control, and the recognition of this responsibility has already inspired a movement for integrating different branches of scientific research. One of the most valuable services rendered by the meetings of the British Association is its educational work in assisting that integration, and thus promoting a broad point of view in which the wiser direction of available scientific effort upon national and social problems becomes possible.

The Quantum Theory

The Principles of Quantum Mechanics
By P. A. M. Dirac. (The International Series of Monographs on Physics.) Second edition. Pp. xi+300. (Oxford: Clarendon Press; London: Oxford University Press, 1935.) 17*s.* 6*d.* net.

THIS is the second edition of the celebrated book that appeared five years ago, which has been perhaps the most outstanding book written on the quantum theory. The new edition has the same brilliantly distinctive style as the old. Much of the book has been rewritten, and a new chapter on electromagnetic radiation has been added at the end; but its main character is unaltered. Nevertheless, it must be confessed that on account of the lapse of time the flavour one derives from it is somewhat different.

In 1930, the great rush of discovery was only just over, and the exponents of quantum theory were still rather sharply divided into two camps, according to whether the wave-function or non-commutative algebra was regarded as the key idea of the theory. There was, of course, no contradiction involved, but tastes differed so strongly that one could really speak of rival schools. Dirac was a strong adherent of the non-commutative school, and from his book one would scarcely have gathered the predominating position in the subject that the wave-function has gained. Indeed, though, of course, he makes extensive use of such functions, he seems to regard them as a slightly discreditable confession of weakness. They constitute an admission that a perfectly abstract scheme cannot conveniently be made so that it will contain nothing but strictly observable quantities. He gives special warning against the analogy with actual waves, and the warning may be justified because the analogy is so good (at least for a single particle) that one is in danger of forgetting that it is only an analogy. On the other hand, he is much concerned with emphasising the analogy between the quantal and the classical mechanics; indeed, the development of this relationship is the spirit that animates the whole of the book.

During the last five years, the conflict of tastes has died down in the way that is usual in science, by the recognition that there was nothing to quarrel about. On the other hand, as a technical method the wave function has won all along the line. Except in one or two special subjects, no one now ever thinks of commutation rules, and even the matrix, not so long ago an almost sacred mystery, is now a perfectly natural feature of the integral calculus. There are two main exceptions to this statement. The commutation rules for angular momentum have a specially simple character, and since angular momentum governs most of the structure of atoms and molecules, the more purely dynamical methods have, in the hands of some, proved fruitful in the study of the closed system of the molecule. The second case where the dynamical methods are used has the honourable, though rather depressing, character of a 'forlorn hope'. There are some subjects which belonged to the classical scheme, but which do not fit at all readily into the quantal scheme; we are thinking in particular of electromagnetic radiation, which is discussed in the new last chapter. In such a case, the non-commutative methods make the fit distinctly less unsatisfactory, whereas the undulatory methods make the subject nearly incomprehensible. We must be thankful for the life-belt which keeps us afloat an extra half-hour, even if we drown in the end.

In the preface to the new edition, the author explains that he has made the book less abstract than before so as to appeal to a wider circle of readers, but it is not very clear what sort of readers he had in mind when he made the alterations. It was easy to see who should be the readers of the old book, for the list would include everybody who had any interest in the quantum theory, provided that he had acquired a considerable preliminary knowledge of the subject from other sources. Though the new work does not demand the same abstractness in outlook as the old, it still calls for the same amount of preliminary knowledge. For example, the first four chapters discuss 'states' and their 'representations' with no mention of what is being described or of how it is going to be done. The generalisations of these chapters will be most helpful to anyone thoroughly familiar with the technique of quanta; but they could not possibly serve as an introduction before that familiarity has been acquired, if only for the reason that no one is ready for a general idea, however well it may be presented, until he has a number of examples to attach it to. Moreover, the book calls for a knowledge of other subjects on a rather high level, and no student with any independence of character would tolerate being kept in deliberate ignorance of the main subject while he laboriously acquired all this ancillary knowledge. For example, a main idea in the book is the analogy between the quantal and the classical

'Poisson brackets'. This analogy was most valuable in Dirac's hands as a guide to the discovery of the quantum mechanics; but once found, its utility is gone because the classical Poisson bracket is a troublesome thing and much more complicated than the quantal, so that most students will profitably desert the rather arid fields of higher classical dynamics, and will devote the time saved to more interesting matters.

One character of the work is to be highly commended, and that is the author's refusal to waste time over rigorous discussions of unimportant difficulties. We may paraphrase his way of dealing with such difficulties in the words: "Though something seems a bit wrong, it can't be really serious, and with reasonable precautions there is no danger." To the rigorist, this sort of thing may be shocking, but it is typical of the author's peculiar genius in being able to use a deeper formalism than can anyone else without allowing it to overmaster him. In the same way, he does not start the quantum theory with five axioms and eleven postulates, or whatever it may be, in the way so dear to the logician, but instead describes some of the physical phenomena which demand a modification of the classical mechanics, and builds up his theory from these. He is consequently free from the danger which lies at the root of all such logical systems, that when they fail it is not the fault of any of the postulates, but of something which was so completely taken for granted that the author never knew he had assumed it.

In this work (and in some others of the Oxford series) there is a bibliographical inconvenience, which proves a quite intolerable nuisance to the reader. There are frequent back-references in the text, which are nearly always in the form :—"In equation (31) of Chapter V it was shown that . . ." At the head of every page stands the number of the section and the title of the chapter, but not the number of the chapter. Consequently in looking up every such reference it is first necessary to turn back and find the table of contents at the beginning of the book.

We fear that in the above account there may have appeared a certain lack of enthusiasm for what is undeniably a great work. This lack is to be interpreted only differentially, in the sense that we do not consider the new edition any better than the old. In the old edition, the author succeeded so admirably in expressing his philosophy that the new was almost bound to disappoint our expectation of still better things. C. G. D.

Temperature and Living Matter

Temperature and Living Matter
By Prof. J. Bělehrádek. (Protoplasma-Monographien, Vol. 8.) Pp. x+277. (Berlin: Gebrüder Borntraeger, 1935.) 18 gold marks.

IN accordance with the general lines of this series of monographs, the author restricts himself almost entirely to cell physiology; ecology and behaviour are not dealt with.

The first chapter is of an introductory nature, and is short. In the next three the author proceeds to an exhaustive discussion of the effect of temperature on the rate of biological processes, and its physical and mathematical interpretation. He explains the theory of the Q_{10} rule and the Arrhenius equation, and points out objections to their use as a means of manipulating experimental data. In particular, he takes exception to the use made of the Arrhenius equation by Crozier and his school. He proposes to substitute for these formulæ a simple empirical equation of the form $y=a/t^b$, where y is the time occupied by the process, t is the temperature, and a and b are constants, the latter having the meaning of a temperature coefficient. This coefficient, b, has, of course, no theoretical significance; but the author claims that it is constant over the whole temperature range in many processes in which other coefficients are found to vary with the temperature.

The classification of biological processes into 'physical' and 'chemical' on a basis of temperature coefficients is unsound, since many physical processes have high temperature coefficients; to make deductions as to the biochemical nature of these processes from their temperature coefficients is clearly still more rash. Bělehrádek's interpretation of the effect of temperature is as follows: Others have tacitly assumed that a chemical process is always the limiting factor in biological reactions, but there is no reason why a physical process, for example, diffusion, should not be limiting, since it can be shown that a high temperature coefficient is not incompatible with such a process; for if diffusion is limiting, it will be affected by the viscosity of the protoplasm, and the rate of the biological process will thus bear the same relation to temperature as does protoplasmic viscosity. The author then proceeds to adduce evidence in

support of his views, and although the theory has met with much criticism it is set forward very convincingly in this book.

The next three chapters deal with the effects of temperature on the chemical, morphological and physical properties of living systems. The question of viscosity is discussed at length, which is not surprising in view of its importance in relation to the author's theories.

Chapters viii and ix concern the relation of living matter to low temperatures, involving discussion of cold-hardiness, chill-coma and the causes of death by freezing. Evidence is brought forward to support the suggestion that chill-coma and the fatal effect of low temperatures (apart from freezing) are due to the increased viscosity, which practically stops all biological processes.

Chapter x, the longest in the book, is devoted to injury by heat and heat resistance, and the last chapter, an account of the stimulative effect of temperature, is necessarily short since a consideration of sense organs and behaviour is beyond the scope of the book.

The first four chapters cover ground which is of fundamental importance to all students of experimental biology. Throughout the book, the systematic arrangement of facts makes it a valuable addition to any library, even though these facts do not lend themselves to any very comprehensive generalisations. The size of the bibliography bears witness to an amount of work for which Prof. Bělehrádek deserves the gratitude of all biologists.

J. A. R.

Motor Fuels

The Principles of Motor Fuel Preparation and Application

By Prof. Alfred W. Nash and Dr. Donald A. Howes. Vol. 1. Pp. xiv + 538 + 9 plates. Vol. 2. Pp. xiv + 523. (London: Chapman and Hall, Ltd., 1934–1935.) 30*s*. net each.

THE reputation of Prof. Nash as a teacher and leader in the petroleum industry is such that any book from him is assured of a sympathetic reception. He has had the assistance of Dr. D. H. Howes, of the Anglo-Persian Oil Co., and his venture is launched with a foreword from Dr. A. E. Dunstan, in itself no mean recommendation.

It is common knowledge that one of the wonders of the world, something which is influencing the daily life and comfort of every one of us, is the modern high-speed, high-efficiency internal combustion engine. This requires fuel to drive it, and so a variety of problems have been set to the oil chemist which are by no means solved, and therefore still in the forefront of interest.

Knowledge, when it has a bearing on everyday life, travels apace, so that even the schoolboy and his sister talk glibly of anti-knock and gumming. The use of petroleum on its present scale is relatively a new thing; it is said that up to the present only two thirds of a cubic mile of oil has been used, and the rate of progress, which is amazing, is largely due to the fact that science has from the outset been so largely applied to the problems. As Prof. Nash says, a team of geologist, petroleum engineer, refinery chemist, business man, and sometimes physicist and mathematician, to which we would add men of energy and enterprise, has co-operated to discover, produce, refine and distribute petroleum and its products. As motorists, most of us expect to be able to stop by the roadside and refuel at a wayside pump almost at will, and it is not realised how great an organisation, how much technical effort is behind this most efficient service.

The work as a whole is divided into two volumes, of which the first deals with the production of the motor fuels by distillation, cracking, extraction from natural gas and hydrogenation. It also deals with the rival fuels not originating from petroleum, for example, benzole and alcohol. The problems of oil storage, insurance and distribution are also briefly touched upon. The second volume describes the subjects of analysis and specification, the 'gum' question, which is one of importance, internal combustion and Diesel engines and knock ratings. A chapter is devoted to aviation fuels.

The primary object of the refiner is to obtain from crude petroleum a fraction which distils over a range from 35° to 200° C., which is redistilled, etc., to marketable petrol: the book is not concerned with the subsequent operations to lubricating oil, fuel oil and asphaltic products.

Straight distillation only yields a proportion of petrol according to the nature of the crude, and as petrol was the most valuable product, means were sought to increase the proportion and were discovered in the process of cracking. In general, during cracking, low boiling constituents are produced by the breaking down under the influence of heat of the larger molecules present in the oil,

some hydrocarbons of even greater complexity being produced at the same time. Though simple in principle, cracking has offered many difficulties in practice: it is largely practised, and the total amount of petrol yielded by a ton of crude oil has materially increased in consequence, thus helping to conserve the world's oil resources.

At the well-head a great quantity of gas is liberated saturated with the lighter liquid hydrocarbons, though in itself it consists mainly of methane. It is customary and necessary to scrub out these liquid fractions before the natural gas can be pumped great distances, so there is available a considerable quantity of highly volatile spirit which is blended so far as possible with the ordinary distillates. There is naturally a limit to this blending process, and at the moment the large amount of butane for which there is no use remains one of the problems of the industry.

Every means is thus taken to obtain the maximum amount of motor fuel from a particular crude oil, which then is subjected to a drastic refining process so as to remove all constituents likely to be harmful to the engine of a motor-car, in particular the sulphur compounds—this subject receives full treatment by the authors.

In countries like our own, where there is no natural source of oil, other home sources of fuel naturally receive consideration. One of these is benzole, a by-product of the coking and the gas industry. The first effort to market this by William Butler of Bristol in 1903 was not very successful, and it was not until the formation of the National Benzole Association in 1919 that a satisfactory marketing organisation for this product, which is sold mixed with petrol, was attained. To-day 'National Benzole' is a well-known product, and the quantity of benzole produced in Britain is continually increasing, though it remains small compared with the total amount of motor fuel.

Considerable interest is attached to a second motor fuel, namely alcohol, which in many lands is likely to be widely used as the result of legislative enactments. The advances in fermentation technique, the use of cheap molasses as the source of sugar and the discovery of processes of dehydrating alcohol so as to make an anhydrous product miscible with petrol in all proportions, have done much to make alcohol practicable as a motor fuel and competitive so long as petrol bears its present high rate of duty. Methods have been worked out for making alcohol from ethylene gas, and where this is available in quantity the process is also a commercial one. If the supply of petrol failed or the product became very costly, there is no doubt alcohol could largely take its place. A lengthy chapter is devoted to the intricacies of this question: it handles also the production of methanol from water gas and the use of this alcohol as a fuel.

The production of oil from coal, either by low-temperature carbonisation or hydrogenation, is as yet in its infancy, though there is a certainty that progress will be made in both directions during the next decade. Such oils are to be regarded as home-produced crudes of special character, and they will come into the hands of the refiner for treatment. In comparison with the processes discussed, the crude oil obtained by distilling shale is barely competitive, and in normal times cannot be regarded as a serious source.

Prof. Nash has given us a scholarly and informative work which should have wide patronage. He makes clear the advanced state of the industry as regards scientific knowledge and the amount of research and development which is taking place. It is satisfactory that there are in Great Britain schools of petroleum technology of university rank and high standing. It is desirable, however, that the practice of refining be also encouraged by every possible means, lest from lack of practical operation we lose contact with what perhaps are the most forceful developments of the day in chemical engineering technology. E. F. A.

The New America: the New World

By H. G. Wells. Pp. 96. (London: The Cresset Press, Ltd., 1935.) 2*s*. 6*d*. net.

STRESSING the general problems rather than details, Mr. Wells in a series of four short but brilliantly written chapters emphasises the necessity for the deliberate readjustment of the social mechanism, so as to realise the possibilities of human expansion that are now running to waste and disaster. He holds that, if an effort is to be made at all to find a way out from catastrophe to a new lease of life for civilisation, the main part of it should come from America, as no other country has the necessary freedom of speech and mind left and all other communities are confused by the war threat.

During his recent visit to America, two aspects of that country's effort to adapt itself to the new conditions seemed to Mr. Wells unique. The first is that the struggle to reconstruct in America goes on in an atmosphere of unbridled public discussion, whereas in Britain it is restrained by habit and custom and by the centralisation of the Press in London. The second is the relative unimportance of large mass antagonisms. There is no widespread conception of a class-war ruling the situation as in Russia, or of racial incompatibility as in Germany or any such exacerbation of xenophobia as in Italy or Japan. There are conflicts of regional interests, indeed, but little regional bitterness.

Practical Applications of the Punched Card Method in Colleges and Universities

Edited by G. W. Baehne. Pp. xxiii+442. (New York: Columbia University Press; London: Oxford University Press, 1935.) 22*s*. 6*d*. net.

THE use of tabulating machines of the Hollerith electric or other types for statistical and recording work of all kinds has increased to a remarkable extent during the past fifty years. It is not, however, generally appreciated how valuable these devices have proved themselves not only in large-scale and intricate accountancy systems but also in actual statistical research in the wide and varied field of social science. The present work describes their use mainly in colleges and universities, for example, in the registrar's and business office and miscellaneous administrative applications, and in psychological, educational, medical, hospital, legal and agricultural research. In their present wonderfully improved form, the Hollerith machines work automatically with such speed and unerring accuracy in complicated statistical manipulations that, to the uninitiated, they seem like uncanny 'robots' of superhuman efficiency.

The experience of the large number of American universities and other institutions here recorded shows that both in the ordinary business routine of a registrar's office and in social research of every kind, such mechanical devices are proving to be increasingly necessary, as essential indeed as mathematics, and are, as the editor rightly insists, the natural outgrowth of the statistical method of approach to modern learning. One writer in the authoritative series of papers here presented from many fields of university and institutional activity expresses the view that, with the statistical approach so perfected by these means, a precision and dependability of research in the social sciences will be secured second only to that of the physical sciences. So far from mechanising thought, the vast reduction in time spent on laborious routine will increase the time available for clear and original thinking and accurate observation.

The Aliphatic Free Radicals

By F. O. Rice and K. K. Rice. Pp. 204. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1935.) 21*s*. net.

THE capture of particles elusive and ephemeral by Paneth and Hofeditz has proved a turning point in the century-old controversy around the question "Do free radicals exist?" In justice to recent developments, the Faraday Society's discussion in September 1933 centred chiefly round entities falling within the definition: "Free radicals are complexes of abnormal valency, which possess additive properties, but do not carry an electrical charge and are not free ions". The book under review is concerned with such radicals, of which "the most striking property is their short life".

The detection and incidental synthetic uses of free methyl, methylene and ethyl are lucidly described, and a hypothesis of thermal decomposition of organic vapours, consistent with many of the data, is based on the intermediate formation of free radicals. The authors are bold enough to prophesy in detail the courses of numerous reactions not yet investigated. Cognate reactions in the liquid phase are briefly discussed, and the hypothesis is extended, with some success, to the decomposition of large non-volatile organic molecules of the recurring-unit type. There are a few slips, such as the description of methyl and ethyl nitrites as "the methyl and ethyl esters of the alkyl nitrites" (p. 138).

Readers interested in the mechanism of reactions will, however, find this a useful, well-produced book with a comprehensive up-to-date bibliography limited by the scope of the title, but the price seems rather high to command a ready sale to individuals.

The Hardness of Metals and its Measurement

By Dr. Hugh O'Neill. Pp. xiv+292+24 plates. (London: Chapman and Hall, Ltd., 1934.) 25*s*. net.

ALTHOUGH the hardness of a substance is not a physical constant, and cannot be expressed as a function of known physical constants, the idea of hardness is a familiar one, and empirical determinations of hardness play a great part in the study of materials. Methods depending on scratching now take only a subordinate place, and 'resistance to indentation' is the most generally accepted definition of hardness. The Brinell test, in which a hard ball is pressed into the object under a known load, forms the basis of most hardness testing, but the introduction of the diamond pyramid, as in the Vickers test, in place of a steel ball, has given greater precision to the test.

The author of this useful manual has made a special study of hardness, and is known as an investigator of the subject. Besides a clear account of the methods of determining hardness in the laboratory and in the workshop, the book deals fully with the influence of the time factor in deformation and with the relation of Brinell hardness to such mechanical properties as tensile strength and capacity for work hardening. The author emphasises the value of 'Meyer analysis' in the investigation of the latter property. Such subjects as resistance to abrasion and the cutting quality of tools and cutlery are also discussed. The manual will be found of the greatest value as a work of reference. C. H. D.

Esquisse du progrès de la pensée mathématique: Des primitifs au ix^{e} Congrès international des Mathématiciens.

Par J. Pelseneer. (Bibliothèque scientifique belge.) Pp. 161. (Paris: Hermann et Cie, 1935.) 15 francs.

IT is not the technical results of mathematical progress, but rather the development in the outlook of mathematicians, which is very ably sketched in this little book. From the primitive attempts of reckoning to the dizzy heights of contemporary mathematics, we thus have before us an ordered and most suggestive exposition of the mathematical atmospheres of the ages. Selected quotations from the leading mathematicians help us to understand the progressive changes in their interests and methods. This is an interesting contribution to the history of science. T. G.

Education and Freedom*

By Dr. A. W. Pickard-Cambridge

NO one with any power of discernment can have failed to note two opposite tendencies at work in the present day: one, a tendency antagonistic, both in intention and in fact, to freedom; the other, a tendency to lay claim to freedom in ways which it is not always possible to defend. The second of these tendencies is seen in a number of educational theories which would, so far as possible, exclude discipline from life in the supposed interests of free development; and also in a certain impatience with all forms of authority, of which those who are associated with young people have been more conscious in recent years than, for example, before the War. But the other tendency we can see writ large on the recent history and present condition of nations and also reflected in the smaller letters of individual mentalities. In Germany, Italy and Russia we are watching the complete subordination of the individual to the State, not only in his external life and action, but also, so far as education and propaganda can achieve it, in thought and will.

If such phenomena were only presented to us by foreign peoples, they would even then merit our very serious attention; but he would be very blind who did not see the same tendency at work among ourselves. We call ourselves a democracy, and the essence of democracy is that it rests upon the free expression of individual thought; but the rigidity of organisation in our political parties has increased during the present century to an ominous degree, and with it the application of what is called 'party discipline', depriving the individual of all freedom of action and speech, whatever freedom of thought he may privately retain. It is at least equally serious, that some of the constructors of the imaginary Utopias which have been most popular with the younger generation in the last few years clearly envisage and apparently approve of political and educational systems based upon the complete elimination of individuality.

Now if this view is accepted, if it is definitely decided that freedom is not worth keeping, the consequences in the field of education will obviously be accepted also—the strict control of all that is to be taught, and of the method of teaching it; the exercise of thorough-going espionage upon teachers and pupils, and the encouragement in both ranks of the giving of information against colleagues and companions; the supervision of every part of the individual life, so that there may be no loophole anywhere for the intrusion of counter-influences, and no opportunity for the expression of free thought. There may be those who feel that such a state is what ought to be; and I do not now propose to argue with them; but what I have to say is based upon the opposite assumption, that individual freedom, subject to such a minimum of restriction and organisation as is necessary for life as a member of a community, is the indispensable condition of a good and even a tolerable human existence, and that just as the educational systems of coercive States, real or imaginary, are directed to the maintenance of the systems of government and life which have given rise to them, so the educational system of a democratic State, which is based on the principle of freedom, should be directed towards the maintenance of that freedom, and the encouragement of its responsible use. As the principle of the direction of education in accordance with the 'spirit of the State' must necessarily result, in the authoritarian State, in training citizens *not* to think, so education in the spirit of a polity of free men and women must above all train them to think freely and accurately, and to desire to carry the results of their thinking into action. As the former type of State will try to produce a standardised and unresisting mentality, the latter will allow the utmost variety and will look for the good life of the community to the clash in rational discussion of the most diverse views, brought to judgment before the bar of a public opinion in the formation of which all alike may take their part.

The ideal State and community will be a democracy in which every individual is free to realise the highest values, physical, moral and spiritual; and the realisation of some of these is only possible if he can enter into freely determined mutual relations with others, participating fully in the life of the community, communicating his share of good to it, receiving his share of good from it. The community and the State will recognise fully the value of the individual personality, and will acquiesce in no condition which makes any individual merely a means to the well-being of others, or to the stability of the organised

* From the presidential address to Section L (Educational Science) of the British Association delivered at Norwich on September 6.

community, for the sake of which in authoritarian States, real or Utopian, individuality is sternly suppressed.

But the desired freedom of the individual has to encounter obstacles of more than one kind, and it is in a great measure with these that education has to deal. The obstacles are partly in himself, partly in the community. It is obvious at once that no one, as he is, is completely free. Everyone is greatly hampered by the effects of heredity, which, whatever the mechanism, seem to be mental as well as physical; by the influence of body upon mind; by the tendencies imparted by early environment and habituation; and by the results of his own actions. Yet it is probably a fair summary of what may be inferred from common experience, that each individual has at any moment a certain balance or reserve of freedom, that is, of power to act in the way which he recognises to be good—a balance or reserve which he can increase or diminish by every individual act, every exercise of will, so far as he *is* free. Therein lies (as all moralists have seen) the importance of each single action; for it is in the determination of single actions that increased freedom must be won. By constant action in one direction, habits are formed which it is very difficult to break. By repeated choice of the higher as against the lower values, the choice of these becomes easier; freedom is increased. Accordingly, one purpose at least of education is to set what seem to be the higher values before the immature mind in such forms as it can understand, and to encourage the habit of choosing them. About most of these higher values there is really very little doubt, and in such forms as kindness, unselfishness, truthfulness, fair-play, thoroughness, neatness and other elementary kinds of beauty, they are as accessible to young minds as to old.

Further, the importance of discipline depends upon the fact that without it—without a certain external compulsion at times—the immature personality may not discover that it *has* the freedom to choose something other (and, as it will afterwards recognise, something better) than that which immediately appeals to it. Discipline, correction and guidance reveal the power of choice—of doing what you do not want to do; and in time self-discipline follows and freedom increases in proportion—freedom, that is, to pursue and realise ends or values deliberately chosen, because they are recognised as good. No one can possibly be less free than one who has always been allowed to do what he likes; he will never have discovered that he can do anything else. To deprive the young in the name, forsooth, of freedom, of all benefit from the experience of earlier generations—to put *no* values before them as good—is not, in fact, to increase, but to restrict their freedom by denying them the conditions of a fair choice. The young mind has neither the information nor the training to decide everything for itself. But it *is* the object of education and of discipline that it may ultimately have these, and may do some things, no longer because they are imposed by authority, but because they are recognised to be good, and other things, it may be, because the ideas suggested by authority have now been revised and modified by the growing reason. If the discipline and guidance are accompanied, so soon and so far as is possible, by reasons which will not only suggest why it is that such and such acts and habits are good and so cause the discipline to be willingly accepted, but will, above all, help to form the habit of reasoning and of considering what *is* good or bad, the result, so far from hampering freedom, will be to elicit and enhance it.

It is clear that over and above the influence of wise suggestion and example, not only in the general life of the school as a society, but also in the choice of literature, in the study of characters both in literature and history, and in the presentation, in however simple a form, of the working in history of cause and effect, an immense opportunity is open to the teacher.

But education has much more to do in the cause of freedom than the encouragement of a habit of discriminating between good and evil, or better and worse, and the suggestion of the lines of such discrimination. For before life is far advanced, the simple problems and issues of early days are merged in far more complicated issues, requiring the utmost clarity of thinking; and not only does the true discrimination between values itself become more difficult, but also a knowledge of facts, a power of analysing them and appreciating their bearing, and therewith an understanding of the particular conditions in which the realisation of ideals of good has to be attempted, become essential; in short, a clearness of perception and judgment without which the best intentions may end in disaster.

For effective thinking two conditions are necessary: first, that the materials with which thought has to deal shall be so far as possible true, or, in other words, that truth about facts shall be accessible; secondly, that the mind itself shall have been trained to work accurately and honestly; and if freedom in political and private life is to be preserved, those who educate others must put them in the way of obtaining truth about facts and of distinguishing truth from falsehood in what is presented to them and in their own reasoning. It would take a very brave man to deny the immensity of the obstacles. Even in a country so free as our own, the temptations to accept opinion

manufactured by others, not always for the best ends, are enormous.

Yet preparatory work may be done on the lines which are followed, at least in a few schools, in which in some upper forms present-day problems are discussed, or the news of the week presented, in ways which encourage older boys and girls at least to think about them, to be aware of the two or more sides that each question presents, to realise the duty which lies upon them, or will shortly lie upon them as citizens, to get the best information and to form their opinion with a high sense of responsibility and a disregard of the interest of class or self. They can be led to realise that democracy is less a system of equal rights than a system of equal responsibilities; and even the common life of the school can teach them how much one clear and decided mind can do in shaping the opinion of its own circle. The foundation of habits of impartial and critical judgment *can* be laid at school, and if they are not laid there, the odds are heavily against their being laid anywhere else. The teaching of history is an obvious instance of the opportunity which education affords for the formation of habits of careful judgment. As in all other matters, there must be an impartial presentation of facts and issues, and, if possible, opportunity of discussion of a kind suited to the age of the pupils.

In other ways, the dangers of dependent, unventuresome and even servile mentality may be partly met by the school. Young people are much more likely to *think* for themselves, if, subject to the necessary framework of school discipline which is scarcely felt so long as it is wisely controlled, they *do things* for themselves. This is well understood in the older public schools, but I confess that in a great number of secondary schools—and secondary schools are of special importance, because from them should come the leaders of opinion in nearly all those smaller circles in which, much more than on platforms, public opinion is made, as well as most of the future teachers of the mass of the people—I should like to see a good deal more room for independence and self-government. It is impossible to train young people in the free use of judgment without letting them exercise it freely in their own affairs and (with slight and obvious limitations) make their own mistakes, and grow in the power of judging how to act and of understanding the characters one of another; for in a free State, the power to choose persons is as important as the power to choose between policies, and there is no place so good as a school for learning either to lead or to choose and follow a leader.

Again, no one can deny the effect of the mechanised drama, which is the almost universal recreation on certain days in the week, in producing a standard mentality (one might almost say a uniformity of bad taste) and in confining interest to monotonously narrow lines; and the fact that the interest in sport of which our countrymen boast takes, for nine-tenths of them, the form not of healthy personal activity but of massed attendance at the performances, provided for them by no effort of their own, of two teams of hired entertainers or of a few trained dogs, is not indicative or productive of an active intelligence. If education is to counter this, it must encourage those occupations of leisure in which the individual can exercise his own free choice and express himself—the performance (not merely the hearing) of music and drama, the practice of handicrafts, of arts, of gardening, of all kinds of performances which are personal, not mechanical. It must set before the young the infinitely various ways of spending time worthily; and must encourage an attitude towards books and reading which few of our examination-ridden youth attain. For all these things are the activities of free minds, not of those which accept unthinkingly everything which is superficially attractive and is therefore accepted by crowds. Without some such influence from education, we can expect only passive minds, barren of ideas, and unable to rise by freedom of thinking to meet the perpetually changing needs of the world in which they are called upon to live.

As I have spoken of examinations, I had better say explicitly that I rank examinations, not in themselves, but as they are treated in most schools at the present time, among the worst enemies to education in freedom of thought and independence of judgment. Examinations can be, and should be, invaluable aids to education; but it is a condition of this that they should be only an incident in the work of the school, testing at convenient points the work of both teachers and pupils, and really, and not merely by profession, following and not directing the curriculum. Their usefulness is undoubted in training the young mind to do what it will continually have to do afterwards—namely, to bring whatever knowledge and resource it may have to bear on a particular point at a given moment, and in this both intellectual and moral qualities are involved. But where the whole work of the school is planned to cover or lead up to the syllabus of some particular examination; where every subject is studied at a rush in order to work into the pupils' minds what are virtually prescribed answers to questions which may almost be said to be prescribed, so narrow is the range from which they can be drawn; where the teacher does not dare to encourage his pupils to think; where he cannot go at his own pace and cover in his own way the ground which he can effectively cover, for

fear of the effect on the statistics by which the local education authority, knowing little of education, judges the efficiency of his school and his own fitness for promotion, or by which the employer, knowing even less, judges the suitability of individuals for purposes never contemplated by the examination authorities—there examinations are a very mischievous thing. Unless the habit of working and teaching for examinations before everything else is abjured, I see little hope of the type of education which alone can save democracy, and bring up a race of free men and women.

There are other reforms which are urgently needed, if our present system of education is to be brought nearer to the fulfilment of such an end. The prolonging of the time of education is obviously one, provided that the education is of the type which liberates and trains the mind, and does not merely rivet its fetters more tightly. A great reduction in the size of classes in most subjects is another; not necessarily in all subjects, or for all purposes; but such a reduction as will give the individual member of the class a chance, and will enable a teacher to encourage a pupil who has a line of his own to follow it up, and to see that every pupil is mentally active and not merely receptive. Young people have not indeed enough experience to prescribe or to conduct their own studies to the extent imagined by some enthusiasts; but they have minds which should not be allowed to be inert or be driven along precisely the same route as twenty-nine or thirty-nine other minds, and the smaller the class the less the risk of this.

The suggestions which I have made as regards educational practice have nothing new in them, but I have deliberately chosen familiar instances to illustrate my main contention. My object has been to assert that these are no matters merely of theory or of finance or of administrative or political convenience, but of vital and immediate urgency, if we are not unconsciously to bring up a race which, with its mind stunted, its capacity for freedom undeveloped, will be the easy prey of the politician, the journalist and the dictator; and that if a free democracy is to continue, we must educate for it, for in many respects our present educational system is better calculated to produce a servile and passive mentality than to elicit an activity of mind and an independence worthy of free men and women.

We have reached a point in the history of Western civilisation when the forces which make for the enslavement or the inertness of mind and spirit are active as they have not been for centuries. It is therefore incumbent upon us to test our educational institutions and methods at every point by their tendency to produce or to hinder freedom of mind, to cut out all that makes for the standardisation of individualities or is hostile to ultimate independence of judgment, at the same time so setting before the young the higher values, which make for good life and good citizenship, that they may have the chance of freely making them their own. If we can do this, we may yet see the development of a type of humanity richer in freedom, self-discipline, courage and vision than any which the world has yet known.

Recent Progress in the Study of Early Man*

By Sir Arthur Smith Woodward, F.R.S.

WHEN meeting in East Anglia it is appropriate that the Section of Anthropology should devote special attention to prehistoric archæology. In this part of England so long ago as 1797, John Frere made the first scientific observations on palæolithic implements which he had dug out of a superficial deposit at Hoxne. During recent years, Mr. J. Reid Moir has excited wide interest by his discoveries of the oldest known stone implements, which he has collected with remarkable zeal and discussed with acute observation. Here also arose the 'Prehistoric Society of East Anglia', which has been so well supported during its career of more than twenty years, that it has gradually widened its sphere until now it becomes the 'Prehistoric Society', devoted to advances in its subject in all parts of the world. We are, indeed, now confronted with problems much greater than those which the pioneers in western Europe dealt with, when they were laying the foundations of research in prehistory. Traces of men who lived before the dawn of history in widely separated parts of the earth's surface have been discovered in increasing abundance during recent years; and a study which at first was more or less local has now become one of world-wide scope.

Among the several branches of science which contribute to our understanding of the subject,

* From the presidential address to Section H (Anthropology) of the British Association delivered at Norwich on September 9.

those of palæontology and geology are of considerable importance. The period of man's existence on the earth has been so short that there has been no appreciable evolution among the mammals associated with successive human races; but many migrations and extinctions are observable, so that these mammals can often be used for determining the relative ages of the isolated deposits in which human remains and implements occur. In some cases also the mammals are probably enough to show the nature of the climate and the local conditions under which they lived. The contemporary geological changes, though small, likewise help in explaining migrations and perhaps some extinctions; while the peculiar circumstances of the Great Ice Age, under which early man flourished in the northern hemisphere, varied so much from time to time, that they have been used in forming a plausible chronology. As a palæontologist and a geologist, therefore, I propose to discuss some of the latest developments of prehistory.

It has long been recognised that the earliest men of which traces have been found in Europe did not originate on this continent, but were immigrants from some other region. It is thus important to examine the numerous associated mammals to ascertain whence they came; for most of these mammals seem also to have been immigrants to Europe just before or during the Pleistocene period when man began to live here, and they may give a clue to his origins.

Sir W. Boyd Dawkins was one of the first to take a broad view of the mammals which accompanied the successive races of early man in Europe, and he eventually published a map to illustrate their mixed origin. In addition to some which were already in the middle of the European continent, others seemed to have come south from the Arctic regions, others had passed directly west from the middle of Asia, while a few could only be explained as having come north from Africa over old land bridges to Gibraltar and southern Italy. These mammals might not all have lived together, but they at least showed how varied were the routes open to the movements of primitive men.

It now appears that the tracing of the warmer types of mammals to an African source was a mistake. Recent researches seem to have proved that during the Pleistocene period there was no direct communication between Europe and Africa, either through Gibraltar or through Sicily and Malta. Geologists are satisfied that certain shells which are characteristic of northern seas could not have entered the Mediterranean to be found there in Pleistocene sea beaches if the Straits of Gibraltar had not been open. Others have remarked that among the numerous remains of mammals which occur in some of the caves at Gibraltar, there is nothing distinctly African. Dr. Raymond Vaufrey has more recently examined the fossil mammals and stone implements found in the caves and other Pleistocene deposits of Sicily and Malta, and he shows clearly that although these islands were connected with Italy at the time, they never had an extension to Africa.

The latest discoveries of fossil mammals in the caves of Palestine and Syria, as interpreted by Miss Dorothea M. A. Bate, show that during the early half of the Pleistocene period, Asia and north Africa were much more closely connected than they have been since. The country was comparatively well watered, with luxuriant vegetation and forests, and mammals could readily migrate both east and west. Even so characteristic an African animal as the wart-hog (*Phacochœrus*) was then living in Palestine. The connexion of Asia with Africa was thus as definite as that with Europe; and the explanation of the partial identity between the Pleistocene mammals of Africa and Europe is probably that they had a common source in Asia, and diverged west in two different directions, one southwards, the other northwards.

This conclusion is supported especially by the apparent origin and former distribution of the spotted (or cave) hyæna, *Hyæna crocuta*. In the Pliocene deposits of the Siwalik Hills in northern India, there are jaws and other remains of hyænas which are not quite *H. crocuta*, but may well represent its ancestors. By the Pleistocene period, the typical *H. crocuta* was already in existence in India, as shown by a tooth discovered in the Karnul caves, Madras. Remains of the same species have also been found in Pleistocene deposits in central Asia and even in China. They are likewise widely spread over Syria and northern Africa, where only the striped hyæna (*H. striata*) lives to-day. *H. crocuta*, therefore, is not an African animal. It originated in Asia, spread thence in different directions in the Old World, and has survived only in southern Africa, which is at one extremity of its former wide range.

It is also to be observed that none of the characteristically African antelopes occurs among the European Pleistocene fauna. Remains of the gazelle have been found, but this animal is as much Asiatic as African. The Saiga antelope and *Nemorhœdus*, which are Asiatic to-day, are the only other antelopes which reached Europe in Pleistocene times.

The Pleistocene mammals of Europe, therefore, show that when they flourished on this continent, the only direct land communication was through Asia. The earliest races of men must have reached western Europe by that route; and as a succession of stone implements, remarkably similar to that

which is now so well known in Europe, has already been found with early Pleistocene faunas in Africa, it might at first be supposed that there were parallel migrations of the same men from the Asiatic to the African continent. Implements, like languages, however, afford no certain clue to the races which made and used them, and the same tools must have been invented independently more than once. It is therefore unfortunate that hitherto no human remains have been found in undoubted association with any of the earliest implements and Pleistocene mammals in Africa.

Two years ago a committee of geologists which met in Cambridge expressed itself as satisfied with evidence which Dr. L. S. B. Leakey submitted in order to prove that he had discovered modern types of human skull and lower jaw with very primitive implements and early Pleistocene mammals in Kenya Colony. In fact, it appeared as if the same types of implements in the same geological stage in Europe and Africa had been made by two distinct genera of men. Quite lately, however, Prof. P. G. H. Boswell, under the guidance of Dr. Leakey, has examined the geological formations in the region where the discoveries were said to have been made, and he is now convinced that there is no proof of the association which has been claimed. The human remains in question seem to have been obtained from disturbed deposits, and may have been buried at a comparatively recent date. With later types of stone implements and remains of modern mammals, the only satisfactory fragments of the human skeleton which have hitherto been found in Africa belong to the genus *Homo*. Many of the fossil forms are related to the surviving South African bushman, and if any of these passed directly from northern Africa into Spain, as has sometimes been supposed, they must already have learned to make rafts by which they could cross the Straits of Gibraltar.

The only fossil hitherto discovered in Africa, which suggests that that continent may have produced man, is the immature skull from a deposit of uncertain age (probably Pleistocene) at Taungs in Bechuanaland, which was named *Australopithecus* by Prof. Raymond A. Dart in 1925. It belongs to an ape, and seems to exhibit more human characters than the skull of any of the existing apes; but Prof. Dart's complete account of the fossil has unfortunately not yet been published.

The earliest known jaw of an ape, *Propliopithecus*, was discovered long ago in the Oligocene of Egypt, and numerous jaws of apes related to the existing chimpanzee are now being found in the Miocene of south-east Africa. Equally abundant, however, are the jaws of apes in the Mio-Pliocene deposits of northern India, and some of the teeth preserved in them exhibit a remarkable approach to those of man. I still think, indeed, that according to our present knowledge, the links which connected apes with man are most likely to be found in south-central Asia. As the late Joseph Barrell pointed out, the east to west ridge of the Himalayan Mountains was gradually raised up at the time when northern India was covered with a great forest which swarmed with apes of many kinds. The formation of the ridge separated off a northern portion of the forest which became subject to comparatively inclement conditions. The apes stranded in this northern portion would be disturbed by the extensive destruction of the trees, and the survivors would be driven to be ground-apes and change their habits of feeding. They would thus be modified in the direction of man.

These considerations, with the geographical distribution of the few oldest known remains of fossil man, led the late Dr. Davidson Black to make plans for a systematic examination of the later Tertiary deposits of south-central Asia. In 1925 he reviewed the whole subject in an important paper published by the Geological Society of China. In the summer of 1932 he actually traversed a route from eastern China, through northern India, to Syria and the western coast. Dr. Black, unfortunately, did not live to see the realisation of his project, but we are glad to learn that Father P. Teilhard de Chardin will take his place in researches beginning in India this autumn.

It is very interesting to notice that if central Asia was actually the region in which the human family originated, the few known fragments of the oldest fossil men are distributed geographically just as a palæontologist would expect them to be. The late Dr. W. D. Matthew pointed out that if each race of animals evolved at a single centre, a succession of waves of increasingly advanced genera must have radiated outwards from that centre. The latest and highest types would be found at the actual place of evolution, and they would be surrounded by rings of less advanced types of lower and lower degree until the lowest would occur at the outer limit.

The fragments of the oldest fossil men hitherto discovered are indeed very few, but although allowance for negative evidence may cause some hesitation, it is at least noteworthy that they are all on the periphery of the Euro-Asiatic continental area. *Eoanthropus* and Heidelberg man were found on the western margin of Europe, *Pithecanthropus* at the southern margin of Asia, and *Sinanthropus* close to the eastern coast of Asia. If human types were evolving near central Asia, the places of these actual discoveries are in a distant partial ring round the source.

The next stage in man's development is much better known, because by this time he had learned to bury his dead in security. As examples have been found in caves so far apart as France and Palestine, burial had doubtless become a general custom. Many whole skeletons are therefore available for study.

This stage is that of Neanderthal or Mousterian man, which is geologically the latest to retain several specially ape-like characters associated in a single individual. Its Asiatic origin is now still clearer to a palæontologist than that of earlier man. Burials in caves which seem to be approximately of the same date reveal a comparatively high Neanderthal type in Palestine, a low and bestial type in western Europe. On Matthew's principle already mentioned, the first is therefore nearest to the original source. The accompanying stone implements support this conclusion, for whereas in western Europe the implements are merely trimmed broad flakes, in Palestine there are also many narrow blades which resemble those made by later (Aurignacian) man in Europe. The Asiatic type of Neanderthal man was indeed progressing in skill to meet his increasing needs. He appears to show us modern man in the making.

Until typical *Homo sapiens* had come into being, man's only outlet from Asia seems to have been by land in the direction of Europe and Africa. As soon, however, as he had attained this final stage of development he must have been able to construct rafts or boats, by which he crossed the narrow seas of the East Indies to Australia, and perhaps the equally narrow seas at Bering Straits to North America.

Australia is shown by its past and present animal life to have been separated by sea from the rest of the world during the whole of the Tertiary era, including Pleistocene times, and it was isolated too early to be inhabited by the ancestors of the apes. Man is therefore certainly an immigrant from overseas, and we know that he reached the country when various relatively large Pleistocene marsupials were still living there, because a fossil human skull has been found at Talgai in Queensland directly associated with their remains. This skull is essentially the same as that of the existing Australian aborigines, who have retained a mode of life like that of the latest Palæolithic hunters of the mainland.

It is remarkable that very few traces of men who might be related to the ancestors of the Australians have hitherto been recognised in their homeland in Asia. The skulls of *Homo wadjakensis* from an old lake deposit at Wadjak in Java, discovered and described by Dr. Eugene Dubois, may perhaps be placed among them. The skulls named *Homo* (*Javanthropus*) *soloensis*, more recently discovered by Dr. W. F. F. Oppenoorth in an old deposit near the Solo river in Java, seem to be intermediate between the skulls of *Pithecanthropus* and the modern Australian, though they have not yet been described in detail. As many have observed, the skull of Rhodesian man (*Homo rhodesiensis*), from a cave in northern Rhodesia, also exhibits several resemblances to the skull of the modern Australian. Other skulls dug up in South Africa have also been described as exhibiting Australian characteristics. Sooner or later, therefore, fossil ancestral types of Australians will probably be found widely distributed in the tropics of the Old World.

In at least part of the first half of the Pleistocene period there must have been a direct connexion between Asia and North America in the region of Bering Straits. There may have been an isthmus of land, or there may have been only islands and continuous ice; but there was certainly a passage which allowed such mammals as the mammoth, bison, sheep, goat, elk, wapiti, reindeer and black bear to reach America for the first time. So far, there is no evidence that man accompanied these animals, and it may be that by then he had not yet reached the north-east corner of Asia. The woolly rhinoceros similarly never passed from Asia to America, although it was abundant and widely spread through the northern lands in the Old World. Its absence from America shows that in come cases there were impediments to emigration.

The earliest traces of Palæolithic man hitherto discovered in North America date back only to the later part of the Pleistocene period. Last year, Mr. J. Dorsch, when collecting for Mr. Childs Frick, found at Fairbanks, Alaska, some small end-scrapers and conical cores, which Dr. N. C. Nelson recognised as identical with those which he had collected a few years before in large numbers in the Gobi desert. These seem to have been made by some of the latest Palæolithic men; and the only stone implements hitherto found in North America in direct association with the remains of typically Pleistocene mammals show that, when man arrived in that country, he had already learned the supreme art of trimming stone by pressure-flaking. In pattern, indeed, his implements resemble those of Solutrean man in Europe, and even include the familiar Solutrean leaf-shaped blades, besides the characteristic spear points. They have lately been satisfactorily proved to be contemporaneous with extinct mammals of Pleistocene age in several localities, especially in New Mexico, Texas, Colorado, Nevada, and Nebraska.

Some of the typically Pleistocene mammals in the southern part of South America appear to have survived until comparatively recent times.

Man was almost certainly associated with them, but nothing is known to distinguish this race from modern South American Indians. The supposed ancestors of the human family reported by Florentino Ameghino from the Tertiary rocks of Argentina are due to erroneous interpretation of the fossils, as already pointed out by Hrdlička and others.

The first fossilised remains of man in the South American continent were discovered exactly a hundred years ago in the caves of Minas Geraes, Brazil, by the Danish naturalist, Dr. Peter Wilhelm Lund, whose centenary has just been celebrated by the scientific men of Brazil in Lagoa Santa and Bello Horizonte. Under the direction of Prof. Anibal Mattos, three volumes have been published in Bello Horizonte, giving an account of Lund's researches, with a Portuguese translation of his scientific papers.

Some years ago the late Dr. Francisco P. Moreno, Dr. Rudolf Hauthal and I, described the discovery of the dried skin and other remains of an extinct ground sloth (*Neomylodon* or *Grypotherium*), with fragments of other extinct mammals, in a cave in Last Hope Inlet, Patagonia. Here again, the presence of fires, cut and worked bone, and masses of hay cut for food for the ground sloth, led us to infer that man lived in Patagonia with the various Pleistocene mammals which are now extinct.

The races of men who eventually reached New Zealand and other remote islands were so far advanced in civilised life that they scarcely concern a palæontologist. They only interest him on account of the disturbance of the existing wild life and the extinctions which they have caused. The ethnologist now joins the human anatomist in attempting to explain the distribution of these people and to discover their relationships. They occupy a lowly sphere in the *modern* world.

The Meaning of Probability

By Dr. Herbert Dingle

THE subject of probability originated in the consideration of actual but trivial problems. Its obvious attractions as a field for the exercise of mathematical ingenuity soon gave it a predominantly mathematical aspect, and in spite of its application to certain practical activities such as those of insurance companies, and its significance for statistical mechanics, it has until recently been treated as a branch of pure mathematics. Nevertheless, the word has a meaning in ordinary life among those who never concern themselves with mathematics. Such people have often to act without sufficient knowledge to predict with certainty the effect of their actions, and they do so in accordance with the 'probabilities' of the case. They do not calculate a numerical magnitude; they simply act in the way which they feel to be 'most likely' to produce the result they desire. Obviously, it is desirable that the precise scientific definition of probability should approximate as closely as possible to the pre-existing, indefinite conception which directs the majority of our actions. If it does not do so, it is not necessarily illegitimate mathematically or even physically, but it would then be better represented by another word.

Now in recent years probability has entered physics in a much more vital way than previously. This introduces another complication. In order to obtain physical credentials, concepts have now to satisfy certain conditions which mathematics does not impose, and, as we shall see, probability in its customary mathematical sense does not necessarily satisfy those conditions. We have therefore a threefold aspect of probability—an ordinary, everyday aspect, a mathematical aspect and a physical aspect; and unless hopeless confusion is to result, we must either use the word only to represent a conception which is satisfactory from all three aspects, or, alternatively, restrict our application of any narrower conception we may employ to those fields to which it legitimately belongs.

We must notice, however, that even when we have done our best to be precise, the question necessarily retains some vagueness—for two reasons. In the first place, when one wishes to convert an indefinite into a precise conception, one has obviously a certain latitude of choice, just as there was a certain latitude of choice in selecting a particular 'unknown soldier' to represent the general war hero. This affects our attempt to frame a mathematical or physical definition agreeing with our everyday use of the word. In the second place, the very idea of probability, however precise it is made, has an intrinsic vagueness, since, unless it has the value 1 or 0 (speaking in terms of the ordinary mathematical definition), it cannot be inconsistent with any single experiment made

to test it. This affects our attempt to make the physical equivalent to the mathematical definition.

Both these difficulties are well illustrated by the problem which is the subject of discussion between Dr. T. E. Sterne and myself[1]. That problem is as follows: "If A and D each speaks the truth once in three times independently, and A says that D lies, what is the probability that D speaks the truth?" Let us consider first the relation of the mathematical to the everyday treatment of this problem; we will consider its relation to the physical treatment later.

We have here an event (D's remark) to which we want to assign the probability that it has a certain characteristic (truth). We have two independent pieces of information bearing on it: (1) statistics concerning D's statements; (2) a comment by A, whose character is known. The difference between Dr. Sterne and myself is that I regard these pieces of information as completely independent, so that any combination of them is purely artificial, whereas he puts them in the same class, obtains a probability by combining them, and claims that it is significant because it is unambiguous.

Now, as we have seen, there is no final proof one way or the other. I would say that a probability derived from either (1) or (2) by itself would be within the limits of ordinary conceptions —like taking two different victims of the Battle of the Marne for the unknown soldier—but that a probability derived from a combination of (1) and (2) would go outside those limits; it would correspond to the choice of, say, a Crimean warrior. The essential vagueness of the first kind prevents a rigid proof of this, but I can give examples to show where, as it seems to me, Dr. Sterne has been misled.

In combining (1) and (2), Dr. Sterne is combining data which have an obvious but inessential resemblance: they are both concerned with people's statements. But those statements are used in different ways. D's character gives us a statistical probability, but A's character, *in reference to the statement of D in question*, has no statistical aspect; the datum would be unaltered if D had never before spoken. In my review of Sir Arthur Eddington's book, "New Pathways in Science", which originated this discussion[2], I tried to make the two sources of data as distinct as possible by citing an analogous problem involving the 'statistical' and the 'cause-and-effect' probabilities of a horse's success in a race. Here the essence of the problem is the same—we have still two independent sets of data bearing on a particular event—but, the irrelevant superficial resemblance having been removed, it is clear that a combination of those data is quite artificial.

What one does in such problems is, it seems to me, to choose first which kind of data to trust, and ignore the other. A gambler, I imagine (I confess to inexperience in these matters), usually decides in favour of the horse that seems most likely to win, and ignores statistics of what has happened to such horses in the past. Another example may make the point even clearer. If Ohm's law has been experimentally verified 9,999 times out of 10,000, and P, who speaks the truth once in 10,000 times, says that it is true, what is the probability that it is false? My own opinion is that no one would pay any heed to the unspeakable P, but Dr. Sterne's method would give a probability $\frac{1}{2}$—that is, the law would be as likely to be false as true. In the problem of D's statement, I am convinced that if there were any hesitation in one's mind, it would be whether to put trust in A or D: it would have nothing to do with any combination of their testimony.

Let us, however, turn to the physical question, which is by far the more important. One of the chief features of modern physics is the conscious realisation and practice of the principle that no statement shall be accorded physical meaning unless it can be tested by physical experiment. It was on this ground that Einstein rejected the notion of absolute simultaneity of spatially separated events: since there is no physical means of determining absolutely if two such events are simultaneous, there is no meaning in calling them so. It was on the same ground that Heisenberg rejected the simultaneous evaluation of certain conjugate characteristics of a mechanical system: since there is no means of determining, for example, the precise momentum of the system at a definite position in space, there is no meaning in saying that the system has simultaneous position and momentum.

The essential vagueness of the second kind mentioned above therefore seems to rule out probability as a physical conception. If we state that the probability that a certain event will occur is $\frac{1}{3}$, then our statement cannot be checked by seeing if it does occur: whether it occurs or not, the statement may still be either true or false. Yet, in spite of this obvious disqualification, probability has stepped into the place vacated by conceptions which the principle in question has expelled. What is the explanation?

It is simply that probability in physics is purely symbolical: it is a metaphor expressing certain experimental results. For example, we find by experiment that in certain definite circumstances a screen is twice as brightly illuminated at one place, A, as at another, B. Now begins the metaphor. We imagine the light to consist of groups of 'photons', to which we assign the

property of illuminating the screen in proportion to their number; hence we must imagine that twice as many photons fall on A as on B. To enlarge our conception we ask why this is so, but we can get no answer. We must therefore rest content with saying that the 'probability' that a particular photon will go to A is twice as great as the probability that it will go to B. We cannot justify this physically if it is taken in any literal sense because, as we have seen, it cannot be tested. It has physical meaning only if we take it as a metaphorical expression of what we observe. We express the *observed behaviour of many* (arbitrarily imagined) photons by attaching a *hypothetical property to each* of them.

Let us now test the physical reality of the probabilities involved in our problem. The records of D's statements alone give a result (let us call it the 'probability'), $\frac{1}{3}$. A's comment alone gives a result (the 'likelihood'), $\frac{2}{3}$. Dr. Sterne's "association table" gives a result (the 'chance'), $\frac{1}{2}$. The probability and the likelihood are obviously real, for they symbolise the results of experiments which have been made. The chance, however, is in different case. It purports to mean, as Dr. Sterne himself says, that if A says many times that D lies, half of his comments will be true. But there is no experimental evidence for this, for the data do not tell us that A has made more than one such comment. We cannot, furthermore, make an experiment to test it (strictly speaking, a superfluous consideration, for 'chance' is intended to represent not prediction but existing fact), for even if we could bring A and D together, make D speak many times, and induce A to comment on each of his remarks, we could have no guarantee that the conditions would not violate the postulate—that, in fact, A and D would continue to speak truth or lie 'independently'. Hence 'chance' can have no physical significance, for it symbolises, not experimental results but a mathematical process.

The questions involved in this discussion are far more important than may appear on the surface. If the chapter on probability in Sir Arthur Eddington's book had been merely an account of a mathematical theory, it would, in spite of its interest and value, scarcely have called for lengthy controversy in a general scientific journal. It was included, however, because of the importance of probability in modern physical theory, and the reader would naturally suppose that what he was reading about had a physical application. This is a relatively harmless example of one of the most regrettable characteristics of our time. Probability, which enters physics as a symbol for expressing actual observations, emerges in scientific romances, amid the blare of trumpets, dressed as a general custodian of any sort of knowledge or rumour that may drift along, and purely objective systems are spoken of as 'waves of knowledge' or 'waves of probability', as though inorganic Nature is altered when someone speaks about it. The consequence is that the general public is led to believe that Nature is dissolved into pure subjectivity.

It is all the result of allowing mathematics, which is a good servant, to become a bad master. Instead of observation, the true test of physical reality, we are offered mathematical uniqueness. So insidious is this evil that Dr. Sterne appears to find it incredible that I describe as a "meaningless mathematical function" an expression which is immediately seen to be so by the foremost criterion of the physics in which he himself has done such brilliant work. It has even been suggested that mathematics is divine, when it is not even physical. It is much to be hoped that the true relations between mathematics and physics will be clarified, for the sake of both physical progress and general understanding of recent advances of thought.

D's statement	C's statement	B's statement	A's statement
T 27	$D + T$ 9	$C \rightarrow D + T$ 3	$B \rightarrow C \rightarrow D + T$ 1
			$B \leftarrow C \rightarrow D + L$ 2
		$C \leftarrow D + L$ 6	$B \rightarrow C \leftarrow D + T$ 2
			$B \leftarrow C \leftarrow D + L$ 4
	$D - L$ 18	$C \rightarrow D - T$ 6	$B \rightarrow C \rightarrow D - T$ 2
			$B \leftarrow C \rightarrow D - L$ 4
		$C \leftarrow D - L$ 12	$B \rightarrow C \leftarrow D - T$ 4
			$B \leftarrow C \leftarrow D - L$ 8
L 54	$D - T$ 18	$C \rightarrow D - T$ 6	$B \rightarrow C \rightarrow D - T$ 2
			$B \leftarrow C \rightarrow D - L$ 4
		$C \leftarrow D - L$ 12	$B \rightarrow C \leftarrow D - T$ 4
			$B \leftarrow C \leftarrow D - L$ 8
	$D + L$ 36	$C \rightarrow D + T$ 12	$B \rightarrow C \rightarrow D + T$ 4
			$B \leftarrow C \rightarrow D + L$ 8
		$C \leftarrow D + L$ 24	$B \rightarrow C \leftarrow D + T$ 8
			$B \leftarrow C \leftarrow D + L$ 16

If, after this, I may be allowed a word on the purely mathematical question, I would say that, if I have understood Dr. Sterne's contingency table aright, I do not agree with him that it cannot be constructed for Sir Arthur Eddington's original problem. If that were so, it would of course indicate a defect of his method of treatment, because the problem (if we allow the assumption, which must be made in the simplified problem as well as in this, that if D does not lie he necessarily speaks the truth) is unambiguous. I had, however, constructed what I believe to be such a table before his first letter appeared. It is given above.

81 statements by D are considered, and each remark in the table is followed by "T" or "L", representing "truth" or "lie", and by the number of such remarks in the 81 cases. For brevity, the following symbols have been adopted :

→ means "asserts that" ; + means "tells the truth";
← „ "denies that" ; − „ "lies".

It will be seen that only lines 6 and 10 of A's statements satisfy the conditions of the problem, giving 4 cases in which D lies to 4 in which he speaks the truth, so that the 'chance' that D speaks the truth is $\frac{1}{2}$, as in the simplified problem. (Incidentally, it will be noted that A lies every time he makes the statement in the problem, so that it would appear to be impossible for B to deny that C declares that D lies—further evidence of artificiality.)

The "likelihood" I calculate as follows :

The probability that A tells the truth is $\frac{1}{3}$. Hence the probability that B denies that C declares that D lies is $\frac{1}{3}$.

If B denies that C declares that D lies, the probability that his denial is false (that is, that C does declare that D lies) is $\frac{2}{3}$. Hence the absolute probability that C declares that D lies is $\frac{1}{3}\times\frac{2}{3}=\frac{2}{9}$.

If C *does* declare that D lies, the probability that D tells the truth is $\frac{2}{3}$. Hence the absolute probability (that is, the 'likelihood') that D tells the truth is $\frac{2}{9}\times\frac{2}{3}=\frac{4}{27}$.

The 'probability', of course, is $\frac{1}{3}$.

News and Views

British Association: Officers and Meetings

AT the meeting at Norwich of the General Committee of the British Association, Sir Josiah Stamp, General Treasurer of the Association, was elected president for 1936. Sir Josiah, who is chairman of the London Midland and Scottish Railway, was president in 1930–32 of the Royal Statistical Society and enjoys an international reputation as an economist. The office of General Treasurer of the Association has been filled by the election of Prof. P. G. H. Boswell, until now one of the General Secretaries. Prof. F. J. M. Stratton, the other General Secretary, decided not to offer himself for re-election, so it became necessary to appoint two new general secretaries. These offices have been filled by the election of Mr. F. T. Brooks, reader in mycology in the University of Cambridge, and Prof. Alan Ferguson, assistant professor of physics at Queen Mary College, London. The new members of council are Lord Bledisloe, Prof. W. G. Fearnsides, Prof. Julian S. Huxley, Prof. R. Robinson, Dr. C. Tierney and Sir Gilbert Walker. Future meetings of the Association are announced for Blackpool (1936), Nottingham (1937), Cambridge (1938), Dundee (1939) and Australia (1940) ; and it is suggested that a selected party be sent in the winter of 1937–38 to take part in the jubilee meeting of the Indian Science Congress.

A Darwin Commemoration

SECTION D (Zoology) of the British Association devoted the afternoon of September 6 to the commemoration of the centenary of the landing of Charles Darwin on the Galapagos Islands, and of the birth of the hypothesis of the "Origin of Species". He landed on September 16, 1835, and during the five weeks he spent in the archipelago his observations included those on birds and reptiles recorded in his note-book, as quoted by Mrs. Barlow in her letter published in NATURE of September 7, p. 391. The clear differences presented more especially by the finches and the giant tortoises found on the different islands, led Darwin to a highly important line of thought and to the realisation that his facts, if well founded, "would undermine the stability of species". In an introductory address, Sir Edward Poulton gave an outline of the observations made by Darwin on the fauna of the islands, as a result of which he became convinced that he must abandon the idea of the separate creation of species though he was then unable to account for their origin. Sir Edward then reviewed evolutionary thought during the past century, especially in relation to the theory of natural selection. Prof. J. H. Ashworth gave an account of Darwin as a student in Edinburgh from 1825 until 1827 with particular reference to the development of his early taste for natural history and collecting, and concluded that in Edinburgh Darwin laid the foundation of his knowledge of the science of natural history. Prof. G. D. H. Carpenter spoke on Darwin and entomology, and cited examples in support of the theory of natural selection. Prof. E. W. MacBride spoke on Darwin and the problem of the population of the Galapagos Islands, and expressed his dissent from Sir Edward Poulton's views on the value of natural selection as a cause of evolution. Mr. H. W. Parker gave an account of the present distribution of the reptiles in the Islands, pointed out that two of the species found by Darwin were extinct and the others by no means common, and that the danger of extinction of other species had been recently realised by the Government of Ecuador. We hope shortly to publish an account of this interesting commemoration.

Protection of the Galapagos Fauna

THE giant tortoises and large iguanid lizards, which are a noteworthy feature of the fauna of the Galapagos Islands, have been greatly reduced in numbers during the last hundred and fifty years on account of their value as a source of oil, meat and leather. Many species are already extinct, and the numbers of others have passed below that minimum limit beyond which a species is unlikely to recover. Their commercial importance has now largely disappeared, but a new factor has arisen which menaces not only the larger reptiles but also the whole fauna. Pigs, dogs, cats and rats, introduced by settlers and visiting ships, are rapidly multiplying and preying heavily on the indigenous population. The danger has been apparent for many years, but it is only recently that a group of American zoologists, associated with the American Committee for International Wild Life Protection, has prevailed upon the Government of Ecuador to enact legislation to protect the fauna. The British Association has expressed to the Government of Ecuador its deep appreciation of the action taken, and has instructed its representative at the forthcoming International Zoological Congress (Dr. W. T. Calman) to direct attention to the matter. Unfortunately, the full scope of the Ecuadorian decree is not at present known in England, but it seems that permission has been given for many of the islands to be set aside as Nature reserves, and for the protection of the native reptiles, birds and aquatic mammals throughout the entire archipelago. No provision appears to have been made for the enforcement of the decree, but it is hoped that an international committee may be formed to co-operate with the Government of Ecuador to achieve this end; Sir Edward Poulton and Mr. H. W. Parker having been nominated by the British Association as its representatives.

Science and Population Problems

SIR ARNOLD WILSON'S public lecture to members of the British Association and others delivered at Norwich on September 9, which dealt with "Science and Population Problems", was a striking illustration of the manner in which the Association may contribute to the discussion of current problems of public policy and government. On these occasions of general assembly of the members, a considered statement on broad lines reaches a wider audience than that to which it is immediately addressed, and in pointing out the bearing of the results of scientific research on the method of approach to a solution of difficulties of the day, it can help to mould public opinion on sane and enlightened lines. Thus, for example, Sir Arnold Wilson, although showing in the latter part of his address that he had in mind more particularly the practical measures dictated by scientific study for dealing with a stationary or falling population in Great Britain, indicated by his wide survey of the facts, so far as known, throughout the world, that population problems assume a different complexion when viewed as a whole. He restored the perspective, which has been lost in recent discussion owing to post-War developments, by reminding his hearers that if in certain countries a stationary or falling population is a menace, a vast proportion of the world population —in the East alone, at least one third—is in immediate or prospective danger of under-nourishment or even starvation through pressure of population and economic stress. This fact, which was patent before the War and was emphasised time and again by the late Prof. J. W. Gregory, has been allowed to fall into the background in the discussion of more insistent social and economic sectional problems. Its implications are no less grave than they were, and call as urgently as ever for consideration—possibly along the line of the scientific study of the distribution of commodities.

Further Exploration of Zimbabwe

NOTWITHSTANDING the general acceptance of the results of Miss Caton-Thompson's excavations in Rhodesia in 1929, a section of archæological opinion in South Africa still adheres to the view that the Zimbabwe are more ancient than was then shown, and the work of a people other than of Bantu stock. It will be remembered that when Miss Caton-Thompson submitted her results to the British Association, on behalf of which her excavations had been carried out, at the South African meeting in that year, Prof. Raymond Dart contested her conclusions, arguing for both the greater antiquity of the ruins and their lack of similarity to anything known in indigenous Bantu culture. An alternative suggestion is that they are of pre-Bantu origin, possibly the work of an Hamitic people under Arabian direction. Further research by South African archæologists, carried out after 1929, tends to confirm, rather than weaken, the view that structures of stone were not alien to early Bantu culture. Such, at least, is the origin attributed to ancient structures, which might, it is thought, have developed into the Zimbabwe, culminating in the unmortared granite towers and walls, thirty feet high and fifteen feet thick, of Great Zimbabwe. It is now reported from South Africa (*Observer*, September 6) that Prof. Dart, who has just returned to Johannesburg from Southern Rhodesia, proposes a further and more intensive exploration of Great Zimbabwe on a scale which will take five years for completion.

Romano-Celtic Temple at Colchester

FURTHER excavation on the Romano-British site at Colchester has revealed more fully the character and purpose of the remarkable enclosure and contained building discovered at Sheepen Farm on the banks of the Colne. The course of the northern wall has now been followed up, and the entire enclosure traced. It is found to be approximately rectangular in plan, except that the north-east corner has been deflected a distance of 155 ft., thus reducing the eastern face of the enclosure to a length of 180 ft. The total perimeter of the enclosing wall is roughly 511 yards. Further details of the enclosed building, of which the purpose is now evident, are given in a

report which appears in *The Times* of September 3. A stepped stone plinth, five feet square, in the centre of which there still remains *in situ* the base of a column of Purbeck marble, 1 ft. 3 in. in diameter, has been found approximately in the centre and in contact with the eastern face of the outer wall of the temple. The steps on the southern face of the plinth still retain portions of the original plaster, and on one fragment of the latter there are faint traces of colour. It is suggested that the column and plinth may be the surviving evidence of an altar which once faced the entrance of the temple. Flanking the plinth to the north and south, at approximately 11 ft. from the north-east and south-east corners of the outer wall respectively, are remains of packed rubble foundations, on which may have stood plinths of a similar nature to that which has been discovered facing the main entrance. At present, owing to their mutilated condition, and until further examination has been made, any conclusion would be premature. The drastic manner in which the temple was destroyed ultimately is, it is pointed out, indicated by the fact that only in the south-east corner of the wall of the *cella* does any portion of the original construction remain.

Funds for Archæological Exploration in Britain

SIR FREDERIC KENYON, in his first presidential address to the Society of Antiquaries of London, which now appears in full in the *Antiquaries Journal*, **15**, 3, stresses the difficulties which beset archæological excavation in Great Britain through the lack of men and money. Of the two, he feels constrained, and rightly, to lay greater emphasis on the latter. Few archæological excavations, he points out, are, like Verulamium, able to 'live on the country' and rely for any considerable proportion of their cost on a constant stream of visitors. Probably most excavators would regard such a solution of their difficulties as something of a calamity, in view of the constant interruption of their work. In the report of the Council, appearing concurrently with the presidential address, an appeal is made for support for the Society's Research Fund, which at present is not adequate to permit subvention of local funds by any amount which is more than an expression of goodwill. The Society is also faced for some time to come with responsibility for the excavation of Maiden Castle at Dorchester. Archæological exploration on any considerable scale is an especially expensive form of scientific research, and is usually beyond local resources. Sir Frederic suggests that the difficulties of the present situation might be met by the formation of a central fund, administered by such a body as the Society of Antiquaries through the machinery of the Congress of Archæological Societies. If this suggestion were adopted, it need not interfere with local interest, but should rather serve to stimulate it. It would also help to co-ordinate archæological research—a matter of no little moment; but not the least advantage it offers is that it would facilitate prompt action when, in these days of rapid development for building, it might be urgently necessary immediately to follow up some chance discovery.

International Congress of Pre- and Protohistoric Sciences

THE Second International Congress of Prehistoric and Protohistoric Sciences, in accordance with the decision taken in 1932 when the first session was held in London, will take place at Oslo in 1936. The Congress will meet early in August. Invitations and a preliminary statement are now being issued by the organising committee in Norway. The president will be Prof. A. W. Brøgger; and Juhs Bøe, Sigurd Grieg and Prof. J. L. Myres will act as general secretaries. The subscription has been fixed at 25 kr. for members and 12 kr. for associates. Enrolments and subscriptions should be addressed to the Bureau of the Congress, Universitetets Oldsaksamling, Oslo. Those who wish to contribute to the proceedings are requested to inform their national representative on the Conseil Permanent before March 1, 1936, and to forward an abstract of their communication to the organising committee before May next. The representatives of Great Britain on the Conseil Permanent are Prof. J. L. Myres, Sir Charles Peers and Prof. V. Gordon Childe (University of Edinburgh), and Mr. C. E. P. Hawkes (British Museum, Bloomsbury, London, W.C.1), secretaries. The organising committee announces that communications dealing with the topics which have been selected for discussion, as mentioned below, will be especially welcomed.

ON broad lines the arrangement of the proceedings will follow that of the London congress, when the members met in five sections, dealing respectively with human palæontology and the evolution of prehistoric man, the stone and metal ages in the ancient world and as found elsewhere, and the transition from prehistoric to historic. Special attention will be given to the discussion of certain Scandinavian problems in relation to the prehistoric archæology of Europe and the ancient world at large. The topics proposed, which were approved by the Conseil Permanent at Berne in December last, are: the excavations on stone age sites in Finmark of the last ten years, rock engravings in Norway and elsewhere, the Iron Age farms of Norway, the history of Teutonic art forms in the fifth and sixth centuries, and the textiles of Oseberg. It is possible that the domestic animals of prehistoric times and the origin of the runic alphabet may also be included, but this question has yet to be decided. The organising committee is anxious that problems arising out of these subjects should be discussed as thoroughly as possible on broad lines.

Co-operative Buying

IT is now generally recognised in large-scale business that considerable economies can be obtained through the establishment of a central purchasing department, and in the Second Report of the Committee on the Standardisation and Simplification of the Requirements of Local Authorities (H.M. Stationery Office. 6*d*. net), a similar policy is urged on local authorities. The larger local authorities are recommended to co-ordinate the buying of their various departments while smaller authorities are advised to co-operate with other

similar authorities or with larger neighbours. Co-ordinated or co-operative buying is, however, of much reduced value if it is not preceded or accompanied by a fair measure of standardisation and simplification whereby unnecessary variations of type, size and quality can be eliminated. Already the County Councils of Kent, London and the West Riding of Yorkshire have adopted complete centralisation of the buying functions in a supplies department which is independent of other departments; while the City Councils of Birmingham, Liverpool and Manchester have partially centralised the buying functions in those departments which are the largest users of the particular commodity. Manchester City Council saved £17,000 in 1933–34 by determining the best grade of fuel for the heating apparatus at its institutions (thereby halving the number of grades in use), and buying its fuel in bulk and by specification. The Committee strongly emphasises the point that bulk purchase if it is accompanied by standardisation and simplification enables better goods to be bought with less money, but that bulk purchase cannot be operated with maximum success unless the requirements of the buying unit are large enough to command large-scale buyers' terms and to employ experienced staff.

Influence of Industrialism on Mortality in Japan

IN a recent report of the Institute of the Science of Labour, Kurasiki, Japan (No. 29: (1) Sex-Ratio in the Population of Japan Proper; (2) The Influence of Industrialism upon the Mortality of Young People and Adults. By Dr. Sinzi Katuki. Pp. 30. Kurasiki: Institute for Science of Labour, 1935. 60 sen), Dr. Sinzi Katuki writing on the influence of industrialism upon the mortality of young people and adults shows that there is in Japan a close correlation between the female death rate in the age group 15–44 years and the rate of migration from the rural to the industrial areas. The death rate among women workers exceeds that of males in every industry except mining. Dr. Katuki concludes that these facts suggest the grave responsibility of industry for the heavy death rate of Japanese girls and young women, since in Europe and America, although employment of women is extensive, the female death rates are much lower than in Japan, absolutely and relatively to the male death rates. It would therefore seem that the high death rate of Japanese women in this age group is the result not of industrial labour in itself but of the bad conditions under which it is carried on and the insufficient protection of female workers. Recent statistics show a remarkable increase in the industrial occupations of women in Japan. Whereas formerly the great majority of women engaged in industrial employment regarded it merely as preparatory to marriage or only as a subsidiary means of subsistence, it has now frequently become their permanent and essential means of livelihood.

Synchronisation of Radio Stations

THE effect produced when a wireless set receives two different programmes on the same wave-length, although the stations may be widely apart, is sometimes called 'radio hash' in the United States. The Federal Communications Commission spaces two stations producing the same wave-length as widely apart as possible, but according to a report issued by Science Service, Washington, D.C., the whole country is spotted with these 'hash' or interference areas. In the June number of *Electronics*, the editor of which, Dr. C. H. Caldwell, was formerly a radio commissioner, a method of synchronising several stations on a given wave-length is described and thus space could be saved in the broadcasting spectrum. If the plan were carried out, no less than 1,527 radio stations could be constantly working in the present 106 channels. If all the stations, on a great nation-wide 'chain programme', broadcast only on three adjoining channels, 750, 760 and 770 kilocycles, for example, then it is only necessary to turn on one of these to get the corresponding programme. If one turns to other wave-lengths, then other chain programmes are obtained. In addition, low-powered stations, one kilowatt, for example, could be working —twelve to a broadcast channel—throughout the country. These programmes would be sharply differentiated from the 'chains'. Ten channels would be allotted to Canada, Mexico and Cuba, all of whom are asking for more space on the ether. For the American farmers there would be seven channels for superstations up to 2,000 kilowatts, so that every farmer, however remote, could hear. The 1,500 new stations could be heard with less interference than the few hundreds they would displace.

Express Highways in Germany

GOOD progress is being made in the construction of express highways (*autobahnen*) in Germany. An article in *Roads and Streets* gives an illustrated description of some of these highways and incidentally gives a photograph of part of an old Germanic plank road, built about 1000 B.C. and excavated a year ago at Bremen. The first 1,000 miles of the express highway has been completed. Most of it consists of a lawn strip 15 feet wide bordered by traffic lanes 25 feet wide on each side, the sides of the whole road having 'shoulders' sloping upwards. Trees and shrubbery are planted on the centre strip and on the shoulders. The shrubbery in the centre strip protects the driver largely from the glaring headlights of cars travelling in the opposite direction. Densely wooded areas are relieved at intervals by small clearings giving views of distant landscapes. There are no crossings, viaducts or subways being provided so as to permit continuous and fast travel. Twelve of the German universities have laboratories for testing road building material. At Braunschweig there is a test track about 1,000 feet in diameter where tests are carried out on different types of surfaces under traffic conditions. The effects of the velocities of the vehicles on different types of tyres and the abrasion of the roads are all studied practically. The testing of materials for the eastern section of Germany, which is separated from the rest of Germany by the Polish Corridor, is done in the Free City of Danzig. It is hoped that the political difficulties which this Corridor will present to through traffic will soon be overcome.

Scientific Research in U.S.A.

In his report for 1933, the president of the Carnegie Institution of Washington has directed attention to the difficulties which beset scientific research during periods of political uncertainty and retrenchment. "Periods of emergency give rise to shifting conditions which may tend to press toward extinction of research and research institutions through financial weakening, and because of emphasis on what may be considered essentials of life." But on the other hand, emergencies present tests of adequacy in research as a method and of the human value of specific ideas for the origin of which it is responsible. The president says it is difficult to visualise a situation in which we could retreat from the present position. "The needs of civilisation can never be met by a static condition in which the generations merely settle down to life at a particular level. One can assume that through coming ages the requirement for increased knowledge with new ideas and their bettered application will grow. Unusual constructive ability arising out of what is known as the scientific interpretation will have an increasingly important part in development and organization of society. The investigation process, both as a means of securing ideas and as a method for learning their application, will naturally and properly take its place as one of the most nearly indispensable of all activities upon which the future well-being of mankind depends."

Cave Exploration

Now that the formation of a central body devoted to spelæological research in Great Britain holds out the prospect of a more systematic promotion of this branch of scientific studies, it is interesting to note the progress made in other countries towards the attainment of a like object. An article by M. R. de Joly, president of the Spéléo-Club de France, in *La Nature* of August 1 rapidly surveys recent activities in cave exploration, but touches in greater detail on the explorations in France of his own organisation. The Spéléo-Club de France was founded so recently as 1930, largely through the enthusiasm of M. E. A. de Martel; but already its members have explored or visited no less than six hundred caves, mostly in the Basses-Alpes, and some presenting considerable difficulties of penetration and no little risk to the explorers. One of the most remarkable feats of cave exploration to which M. de Joly refers was that of the great cave at the foot of the Guadalupe Hills, New Mexico—an area of which the cave exploration is now attracting no little attention in archæological circles in the United States in connexion with the association there of early man with a fauna now extinct. The cave of which M. de Joly writes, although discovered in 1901, was not systematically attacked until 1930, when a subvention from the *New York Times* made possible the organisation of an expedition of fifteen members to spend a fortnight underground. Notwithstanding difficulties of passage, no less than 51 km. were covered, including many chambers of enormous size. Another country which displays great activity in cave exploration is Italy, thanks to official financial support and the enthusiasm and friendly rivalry of a large number of local societies. Three thousand caves have been recorded as explored; and the Italians also hold the record for depth of descent. The Italian caves, indeed, are the deepest known, twelve being more than 250 m. deep, and four more than 300 m., while the deepest of all, the Bus della Preta, near Verona, has a depth of 620 m.

The Rabbit Menace

Wild rabbits have become so numerous in many parts of England that considerable alarm has been expressed by farmers and in the public press at the damage done to crops, pastures and young trees. The University of London Animal Welfare Society has for some years made a special study of the subject. It has now taken a useful and timely step in reprinting in Great Britain, by permission of the New South Wales authorities, a brochure entitled "The Rabbit Menace in Australia in 1933 and the Way Out", by David G. Stead, formerly special rabbit menace commissioner to the Government of New South Wales. The booklet brings strong confirmation to the views previously promulgated by the Society to the effect that the wild rabbit, considered as stock, does not pay, since the damage done by it far exceeds the price received by the farmer; that the trapping industry increases the stock of rabbits instead of diminishing it, and that control of the rabbit-population can be most efficiently (as well as most humanely) carried out by the use of calcium cyanide or similar products yielding hydrocyanic acid gas. The Society has issued several other publications on the subject of rabbit-control.

Treatment of Anæmias

We have received from Boots Pure Drug Co., Ltd., Nottingham, an illustrated booklet describing the different products issued by this firm for the treatment of the anæmias. 'Pepsac' is an active preparation of desiccated hog's stomach, which is given by mouth in pernicious anæmia: 'Hepostab' is an extract of liver specially prepared for intramuscular injection. It is suggested that treatment be commenced with 'Hepostab', especially if the case is a severe one, and continued from the fourth day onwards with 'Pepsac'. Each batch of 'Hepostab' is subjected to clinical trial before issue. Both preparations, and especially 'Pepsac', are of great value in the treatment of subacute combined degeneration of the spinal cord, the most severe complication of pernicious anæmia. Messrs. Boots also prepare liver extracts for oral administration, namely, compound fluid extract of liver—Boots, liquid extract of liver B.P., and dry extract of liver—Boots. For the treatment of secondary anæmias, 'Livron' is recommended: this is an extract of liver, yeast and malt with the addition of a full therapeutic dose of iron.

Medical Research in Egypt

We have received the third annual report of the Research Institute and the Endemic Diseases

Hospital, Cairo, for the year 1933. This shows that, under the directorship of Dr. M. Khalil Bey, much valuable work is being done on the endemic diseases and epidemiology of Egypt. One of the most interesting announcements is the discovery of the intermediate host of a human trematode or 'fluke' parasite, *Heterophyes heterophyes*, first discovered in 1851. The second intermediate host is a fish, in which the cysts of the metacercariæ were found in 1923, and from eating which human infection is derived. The first intermediate host has now been determined, and proves to be a fresh-water snail, *Pirenella conica*, which was found to be infected with the cercariæ of the parasite, and by eating this infected snail the fish become infected.

Lectures on the Rothamsted Experiments

DURING the forthcoming winter, Mr. H. V. Garner, the guide demonstrator of the Rothamsted Experimental Station, and other members of the staff are prepared to give lectures to chambers of agriculture and horticulture, agricultural societies, etc., on the Rothamsted experiments. No fee will be charged for the lecturers' services but any association engaging them will be expected to defray their travelling and hotel expenses and to make such arrangements for the lecturers as may be necessary. The following topics are offered by the member of staff indicated: soil micro-organisms (Dr. H. G. Thornton, Dr. Hugh Nicol and Mr. D. W. Cutler), agricultural botany (Dr. Winifred Brenchley), agricultural chemistry (Dr. E. M. Crowther and Dr. H. L. Richardson), soil physics (Dr. B. A. Keen and Dr. R. K. Schofield), entomology (Dr. C. B. Williams, Dr. H. F. Barnes and Mr. D. M. T. Morland), plant pathology (Dr. J. Henderson Smith, Miss M. D. Glynne and Mr. Geoffrey Samuel), fertilisers, manures, etc. (Mr. H. V. Garner). Further information can be obtained from the Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Announcements

THE late Prof. Ramon y Cajal has left a legacy of 25,000 pesetas to the Spanish Academy of Medicine to found a prize for the best work on a subject to be selected by the Academy.

THE Rockefeller Foundation has made the University of Chicago a donation of 243,000 dollars, of which 168,000 are to be spent on the foundation of a psychiatric clinic.

THE following appointments have been made by the Secretary of State for the Colonies: Mr. J. H. Harris, to be assistant chemist, Geological Survey, Tanganyika; Mr. C. W. S. Hartley, to be agricultural officer, Malaya; Mr. G. B. Masefield, to be agricultural officer, Uganda; Mr. A. F. McKenzie, to be agricultural officer, Sierra Leone; Mr. R. F. A. L. Reed, to be superintendent of agriculture, Nigeria; Mr. W. T. Dalgarno, agricultural instructor, Bahamas, to be superintendent of agriculture, Nigeria; and Mr. E. Williams, superintendent of agriculture, Gambia, to be agricultural officer, Uganda.

THE annual exhibition of the Royal Photographic Society will be formally opened by the president, Mr. Robert Chalmers, on September 13. The exhibition will be open to the public in the Society's galleries, 35, Russell Square, W.C.1, on September 14–October 12, from 10 a.m. until 9 p.m. (Sundays excepted), except Tuesdays and Fridays when it will be closed at 6 p.m., and lectures given. Admission to the exhibition is free.

THE twenty-second Congress of the Alliance of Social Hygiene will be held in Angers on October 4–6, when the following subjects among others will be discussed: Social medicine and traditional family medicine, extension of the work of social hygiene in rural areas, social value of open-air sports, anti-cancer and anti-venereal disease centres, the campaign against tuberculosis, old-age assistance and the declining birth-rate. Further information can be obtained from Prof. C. Metzger, 36 Boulevard Ayrault, Angers.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

An assistant director of works in the Egyptian Irrigation Service in the Sudan—The Chief Inspecting Engineer, Egyptian Government, 41, Tothill Street, London, S.W.1 (Sept. 16).

A head of the Mechanical Engineering Department of the School of Engineering and Navigation, High Street, Poplar, E.14—The Education Officer (T.1), County Hall, S.E.1 (Sept. 16).

An examiner in the Aeronautical Inspection Directorate—The Secretary (S.2.d.), Air Ministry, Kingsway, W.2 (Sept. 19).

A head of the Chemistry and Natural Science Department and Vice-Principal of the Portsmouth Municipal College—The Registrar (Sept. 21).

A research assistant in physics in the University of Leeds—The Registrar (Sept. 23).

An advisory economist in the Seale-Hayne Agricultural College, Newton Abbot, Devon—The Principal (Sept. 25).

An assistant lecturer in mathematics in the Royal College of Science—The Secretary, Imperial College of Science and Technology, Prince Consort Road, South Kensington, S.W.7 (Oct. 1).

Two assistants in cancer research—The Secretary, British Empire Cancer Campaign, 12 Grosvenor Crescent, London, S.W.1.

A lecturer in structural engineering and mechanics in the Borough Polytechnic, Borough Road, London, S.E.1—The Principal.

Part-time lecturers in automobile engineering, theory, practice, drawing and design in the Polytechnic, Regent Street, W.1—The Director.

An assistant lecturer and demonstrator in the Faraday House Electrical Engineering College—The Principal, Faraday House, W.C.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 439.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Age of the Universe

ONE of the most important problems of present-day astronomy is that of the age of the universe, and one of the most important pieces of evidence is provided by the orbits of binary stars. The ages which need to be seriously considered fall into two groups; the first is that of the so-called 'long' time scale, which is of the order of 10^{13} years, the time the stars would need to have reached their present condition by annihilation of their substance; the second is that of the 'short' time scale—which is of the order of 10^{10} or 10^{11} years, the time needed for the universe to have expanded from small beginnings to its present size. The motions of the stars ought to provide a means of deciding between the two. For dynamical discussion shows that with the long time scale both the linear motions of single stars and the orbital motions of visual binaries ought to show a reasonably good approximation to equipartition of energy; the short time scale, on the other hand, gives nothing like enough time for such an approximation to be established. Thus if the motions of the stars are found to show any marked approximation to equipartition of energy, it is exceedingly difficult to do other than decide in favour of the long time scale.

It is not easy to test the linear motions of the stars for equipartition of energy, for this requires a knowledge of stellar masses, and these are very imperfectly known. Nevertheless, so far back as 1922, Seares found that the linear motions of the stars show a tolerable approximation to equipartition of energy. It is far easier to test the orbital motions, since I have shown that if these conform to the law of equipartition, the number of orbits whose eccentricity is less than e will be proportional simply to e^2. The material collected in the recent new edition of Prof. Aitken's book "The Binary Stars" makes it possible to test this requirement with some accuracy. The agreement with the equipartition law is shown in the following table:

Orbits of Visual Binaries classified by Eccentricity

Limit of e	Observed	Equipartition
$e < 0{\cdot}1$	0	2
$e < 0{\cdot}2$	11	9
$e < 0{\cdot}3$	20	21
$e < 0{\cdot}4$	34	37
$e < 0{\cdot}5$	58	58
$e < 0{\cdot}6$	83	83
$e < 0{\cdot}7$	89	113
$e < 0{\cdot}8$	102	148
$e < 0{\cdot}9$	109	187
$e < 1{\cdot}0$	116	231

In the last column, the total number of stars has been taken to be 231, so as to make the number of orbits of eccentricity less than 0·6 equal to the number actually observed.

Inspection of the table now shows that up to this eccentricity, observation agrees well with the predictions of the law of equipartition; above it there is a marked deficiency of observed orbits. This deficiency can readily be explained by the well-known difficulty of detecting binaries of high eccentricity, and the still greater difficulty of measuring the elements of their orbits with sufficient certainty to justify their inclusion in a catalogue.

The agreement seems to me far too good to be accidental, so that the new material collected by Prof. Aitken would seem to provide strong evidence in favour of the long time scale.

Blood Group Inheritance

FOULKES EDWARDS and Etherington[1] put forward a theory of blood-group inheritance which amounts to the postulation, in addition to Bernstein's three allelomorphic genes causing the presence of one agglutinogen A or B or neither of them, of a fourth allelomorph producing both. This is intended to account "for the observed occurrence of a small percentage of groups AB and O in the offspring of $AB \times O$ matings".

Now supposing such occurrences to be inexplicable by "mistaken parentage or faulty technique" which the authors invoke in other exceptional cases, they might still be explicable by trisomy or by mutation. If AB individuals from such matings are much commoner than A or B individuals from $O \times O$ matings, the mutation hypothesis must be rejected. On the hypothesis of trisomy, the anomalous AB individuals have three chromosomes carrying the A, B and R genes, instead of the normal two. Such trisomy has, of course, been observed both in plants and animals.

The new theory may readily be tested. In the first place, no $AB \times O$ or $O \times AB$ mating should ever give more than two types of offspring, whereas on the hypothesis of crossing-over all four types might be expected. Secondly, an anomalous AB individual from such a mating should give only AB and O children when mated to a member of group O. On the hypothesis of trisomy, about two thirds of the offspring in such families should belong to groups A or B.

Similarly, the hypothesis of trisomy could be tested by Chrustschoff's[2] technique of observing mitoses in leucocyte cultures. Until one or both of these tests has been applied, it would seem that a suspension of judgment is desirable, Bernstein's theory being retained with the proviso that it may ultimately need modification.

Metaphysics of the Physical World

RECENT letters to NATURE commenting upon Prof. Dingle's analysis of the Georgian era in physics express different views on the ultimate status of the physical world. The following discussion offers a foundation upon which all philosophers of science can agree. Philosophical differences arise if one seeks a deeper interpretation of the fundamental principles.

Prof. Dingle has shown that the new physics has been guided by a principle of observability: only those concepts that can be exemplified in observation are to be admitted in physical theory. The philosophical theory of logical positivism also employs the foregoing principle in the form of an empiricist criterion of meaning. The basic theory of the present discussion will conform to this principle.

The physical world consists of tables, chairs and other perceptible things. A thing is something of which aspects are given in perception. An aspect is an immediate datum of experience, for example, the visual aspect of a desk. Initially, the aspects of things are characterised by the fact that they can be given vividly in experience, but a more complete analysis reveals aspects to be functionally related to other aspects. Thus perception involves the vivid experience of aspects and the remembrance and anticipation of correlated aspects of a thing. Accordingly, our first principle concerning the physical world is that some physical things exist to which correlated sets of aspects belong which may be given in experience. The second principle is that the structure of things is exhibited in the structure of their aspects. These two principles suffice for a basic theory of the physical world. It is not possible to question the principles, since they are empirically discernible in the procedure of science.

It would accord with a positivist or empiricist philosophy to rest content with the foregoing principles. But traditional theory of knowledge, or epistemology, considers the ultimate relation between a thing and its aspects and their dependence on experience, and consequently yields a metaphysical theory.

The theory which has been favoured traditionally by natural scientific workers is dualism. The physical thing is assumed to be independent of experience and to produce its aspects by acting upon the observer. That aspects belong to a thing means that they are caused by the thing. Since the structure of an effect is determined by that of its cause, the structure of aspects manifests that of things. In contemporary discussion, dualism is sponsored by Sir Arthur Eddington.

Dualism was developed in the seventeenth century by Descartes and Locke. The empiricist criticism of it by Berkeley and Hume yielded subjectivism and phenomenalism. A thing was declared to be the set of its aspects which were assumed to be dependent on experience. Aspects belong to a thing in the sense of being members of the set of aspects constituting the thing; obviously, the structure of aspects exhibits the structure of things. The independence of things of experience is lost, and hence subjectivism and phenomenalism have been rejected by most philosophers.

In recent years, philosophers have made heroic efforts to work out a theory according to which experience directly presents an independent thing. The neo-realists, for example, have conceived of a thing as a set of aspects which are independent of experience. They thereby seek to retain the advantages of phenomenalism and dualism.

The three theories, dualism, phenomenalism and neo-realism, yield interpretations of the principles that the aspects of a thing belong to it and that the structure of things is exhibited in the structure of aspects. On dualism the two principles are hypotheses, on the two theories which assume direct experience of things the principles are definitions of a thing in terms of its aspects. It is impossible to decide empirically between the several theories, and on this ground the logical positivists would deny meaning to the problem and its solutions.

A position intermediate between the positivist theory which is expressed in our two fundamental principles and the several metaphysical views may be derived from Mach. The essence of a thing is the functional relation between its aspects. This functional relation is the independent feature of the physical things given in experience; the independent reality of the physical world resides in the independence of a system of laws rather than in the independence of substance. Whether one further holds with phenomenalism that aspects are created in experience, or with realism that aspects are merely revealed in experience, seems to be unimportant in that the issue cannot be decided empirically.

A Useful Application of the Principle of Heterogonic Growth

I HAVE come upon an interesting example of the way in which the application of the principle of heterogonic growth may simplify an involved problem. A certain measurement y of an organ or part of an organism is said to show heterogonic growth with respect to some standard measurement x of the organism when the equation $y = bx^k$ holds good over a definite period, b and k being constants typical for each particular case[1]. Heterogonic growth clearly involves a regularly continuous change of proportions.

This example concerns a well-known and widely-discussed study by the late Prof. Weldon on the shore crab, *Carcinus mœnas*[2]. In three different years, 1893, 1895, 1898, he made accurate measurements of frontal width (between the two most anterior 'teeth' on the anterior edge of the carapace) and carapace length, in a large number of young males covering the range 10–15 mm. carapace length, taken from a particular patch of beach in Plymouth Sound. Grouping the data by intervals of 0·2 mm. carapace length, he observed that with increasing size the mean relative frontal width became smaller, and concluded that some selective agency was acting against individuals with a relatively wide frontal aperture, the intensity of selection being assumed to increase with growth. The theory was apparently supported by the asymmetrical curves of distribution of individuals in each group. In the years 1895 and 1898 the frontal width was progressively less at the lowest size and its relative diminution with increase in body size was correspondingly more marked. Selection was assumed to have produced a progressive

change in the average initial proportions of the offspring and, in addition, the intensity of selection was increasing year by year.

This led Prof. Weldon to suspect that silt in the Sound, which was increasing steadily since the building of the breakwater, was the selective factor, and this he claimed to prove by laboratory experiments; crabs with relatively wide frontal apertures died, their gills covered with silt. Apparently an excellent example of effective selection in Nature, it has already been criticised on various scores by the late Mr. J. T. Cunningham[3] and others.

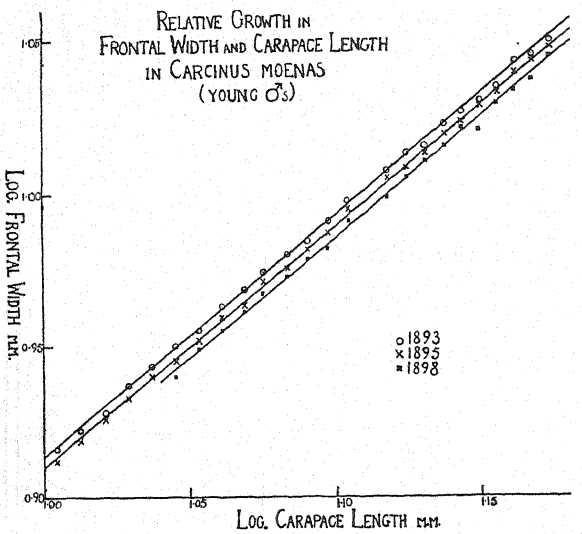

FIG. 1.

Now when the figures are plotted double-logarithmically, frontal width against carapace length, they give a straight line indicating heterogonic growth. The change of proportions which accompanies growth therefore occurs in every individual and automatically, not merely in the group-average, as a result of natural selection. The increase, with growth, of the annual differences, is similarly automatic, given the initial differences in proportion (measured by the constant b). The graphs for the three years are three parallel straight lines (Fig. 1), indicating identical heterogonic growth with a constant growth-coefficient, ($k = 0{\cdot}8$).

The constant b is the only quantity responsible for the differences between different years. However, data are required for more than three years to show whether or not its diminution is continuing. In any event, an explanation is required of its variability. This may be the effect of a variable external condition acting on early development, or even earlier, on the egg, through the parents. Analysis on the basis of heterogony has clarified and narrowed down the problem. In conclusion, it is of interest that young females differ from young males of the same year (1893)[4], but only in the constant b.

Incidence of Rickets in Rabbits

IN the Medical Research Council's Monograph "Vitamins: A Survey of Present Knowledge" (1932) it is pointed out that in Nature, rickets in rabbits is probably unknown, but can be easily produced under laboratory conditions. Furthermore, we can state that under normal conditions of management, the ordinary tame rabbit, as kept in hutches, is also free from the disorder. At this centre, about two thousand or more tame rabbits have been bred, and only three cases of rickets have been seen in the normal stock in nine years; two were in large varieties and one in a medium.

During the years 1927–29, importations of a new class of rabbit, namely, the 'Rex', with fur like the mole and which behaves as a recessive to normal fur, was imported from France and Germany, and this Institute purchased one Castorrex male and a trio of F_1 generation from Rex crossed normal coated stock, all from the same breeder. From the progeny of these animals, a number of rachitic animals appeared. Intensive breeding methods were followed in experimental fur production[1]. The male Rex was mated to normal coated does in May and June, 1929, and from 10 litters, 38 F_1 were grown to adults, from which 9 male and 19 female F_1 were selected for inter-breeding, and from February 1930 until September 1931, produced 524 F_2, in addition to certain other youngsters.

Of the F_2 generation, approximately one per cent of the *rex coated* rabbits had badly malformed forelegs, the condition resembling severe rickets, one *or* both forelegs being convex (bowed), whilst others, less severely affected, had one *or* both forelegs concave (knock-kneed). Closer examination showed some slight abnormality in a few of the normal-coated animals, but in no instance were these more than slight defects. Afterwards some adults were killed for post-mortem examination in the Veterinary Laboratory, and the severe cases confirmed as rickets, whilst a slight case was not confirmed.

Examination of the breeding records showed that rachitic animals occurred mainly in the fourth and subsequent litters, and that the disorder occurred mainly in large families. The average number of young for normal litters was 6·3, for litters in which concave forelegs appeared, 6·9, and for litters containing convex forelegs, 7·4. There was, however, one litter of one with the right foreleg pronouncedly convex. Of 99 F_2 examined for abnormal forelegs there were 79 normal furred and 20 rex furred, of which 10 normal furred (6 were slight cases) and 3 rex coated were concave; and, 3 normal and 9 rex were convex, which is a ratio of 2·96 normal legged to 1 abnormal (rachitic). Other breeders of rex coated rabbits also reported somewhat similar cases of rickets in rex coated but not in normal coated stock. It was, therefore, decided to investigate the possible inheritance of the rachitic condition to see whether it behaved, as indicated, as a simple Mendelian recessive character. However, attempted matings of rachitic with rachitic indicated absence of sexual desire, and in no case would severely rachitic animals copulate with one another.

Ascorbic Acid (Vitamin C) and the Germination and Growth of Seedlings

SCARCELY anything is known regarding the phyto-biological role of vitamin C in the life of the higher plants, and so far as I am aware, no attempt has been made to investigate experimentally their responses when treated with this substance.

The experiments outlined in this note involved the examination of some 2,500 seeds and seedlings. The seeds were germinated on filter paper in Petri dishes, and both these and the seeds were sterilised. The ascorbic acid was dissolved in sterilised distilled water and 3–5 c.c. of this solution was added daily to each Petri dish containing 40–50 seeds. The filter-paper of the controls was moistened with the same quantity of sterilised distilled water. No nutrient substance was supplied, and the experiments were concluded when the reserves of the seeds were exhausted (generally in 12–13 days). The average total amounts of ascorbic acid supplied during this period were, for the different concentrations used, namely, 1/10,000, 5/10,000, 2·5/1,000 and 5/1,000, 4 mgm., 20 mgm., 95 mgm., and 150 mgm.

The observed effects on wheat were as follow. With concentrations of 1/10,000 and 5/10,000: no stimulation of germination, but an acceleration of growth and an increase of 25–30 per cent in the length of the shoots. At the end of the experiments, the weight of the shoots of the treated plants—as compared with the controls—showed an increase of 25–30 per cent and that of the roots an increase up to 50 per cent. A concentration of 2·5/1,000 exercised a slight inhibitory effect upon germination and a very marked one (24–45 per cent) upon the growth and weight of the seedlings. The concentration of 5/1,000 proved to be practically lethal.

Oats were much less sensitive both as regards the stimulatory and the inhibitory effects of ascorbic acid. On the other hand, it was noticed that upon seedlings of plants—such as tomato and paprika—which have naturally a high vitamin C content, a concentration of 5/10,000 was enough to exercise inhibitory effects.

Adult tomato plants treated with a 1/10,000 concentration of ascorbic acid showed no acceleration of growth and flowering, but although the number of fruits produced was less than in the controls, their total weight was 20 per cent greater.

Titration of the vitamin C content of the treated seedlings and tomato plants revealed no increase as compared with the controls.

Swarming of *Vorticella*

WE have observed a phenomenon of swarming in two common species of gregarious vorticellids which has apparently not been recorded hitherto.

Vorticella campanula is found living in crowded groups on pond weed. In an aquarium, the whole population of a group will leave their stalks almost simultaneously and become free-swimming. They do not disperse, but remain for an hour or two suspended from the weed in thread-like swarms. Fig. 1 is a photograph (half natural size) showing three such threads. One of the threads is seen to have a triple base: it arose by the fusion of three threads brought into contact by water movements. Each thread has a mucous core which is collectively secreted by the swarmers, each individual contributing its own mucous strand to the thread. The swarmers, after swimming actively for a time—some very close to the thread, some actually within it—finally settle down again in groups on solid objects.

We have observed this swarming many times, not only in *V. campanula*, but also in another gregarious form, *V. chlorostigma*. Usually, in the latter, the swimming animals collectively form a globular cloud, like a minute swarm of bees. Within this they appear to move quite freely; but the swarm as a whole can be dragged through the water with a needle; and it was demonstrated in other ways that in this species too the swarming individuals are united by mucus. The new sessile groups, formed by the settling of a swarm, sometimes swarmed again after twenty-four hours, and occasionally this was repeated on three or four successive days.

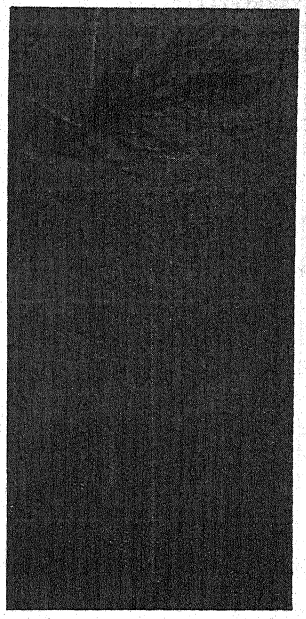

FIG. 1.

We cannot say what is the stimulus that causes *Vorticella* to swarm. Continuous observation, extending over the complete sessile and free-swimming cycle, proved that swarming is not, at any rate immediately, connected with asexual reproduction or with conjugation. Obviously such behaviour, in natural conditions, admirably subserves the dispersal and settlement in contiguity of a gregarious sessile protozoon.

A full account of these observations will be published in the *Proceedings of the Zoological Society*.

Puff and Profile Theory of the Vowels

THE portions of sound film tracks reproduced in Fig. 1 are from registrations of the vowels *oo* (as in *boo*), *ee* (as in *bee*), *ah* (as in *bah*), *ay* (as in *bay*), *æ* (from *a* in *an*). The registration in each case shows a series of contiguous short bits of vibration in each of which the movement begins strongly and fades rapidly to zero. Such a movement occurs only as a free vibration, that is, as the movement of a vibratory system disturbed in its equilibrium and then left to itself. A vibration of this kind is produced when the air in the vocal cavity is rarefied or condensed by snapping the thumb out of the mouth or by closing and suddenly opening the glottis. Such a sudden

rarefaction or condensation may be termed a *puff*. Repeated puffs will produce a series of free vibrations.

To the eye, each bit of vibration in Fig. 1 has a special *profile*. The profiles of the same vowel are nearly, but not quite, alike; those of different vowels are different. The eye learns to recognise the profiles automatically just as it recognises the profiles and portraits of persons; it performs no analysis. No amount of mutilation by lines, blotches or omissions changes the vowel character of a profile. So long as anything can be recognised, it remains the profile of the same vowel; it never changes to the profile of another vowel.

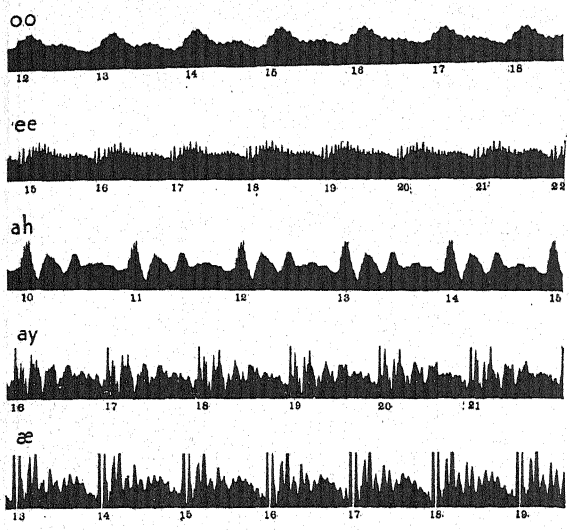

FIG. 1.

The sense of hearing recognises vowel vibrations as the same or different according to their sense impressions, that is, according to the likeness or difference of the profiles. There is no analysis. Experiments in filtering[1] show that any frequency or range of frequency can be removed from the vowel vibrations without changing the vowel character. So long as anything is left, the vowel remains the same one; it never changes to another vowel. The law of no change of speech character by mutilation is valid here also.

The puff and profile theory agrees with that of Willis-Helmholtz-Hermann in regard to the *production* of vowel vibrations by the action of glottal *puffs* on the air in the vocal cavity. It is opposed to it in asserting that the *perception* of vowel characters depends on the unanalysed *profiles* of the vibrations and not on any special frequencies or groups of frequencies.

Magnetism of Copper

A LARGE amount of experimental evidence has been recently put forward to show that colloidalisation of certain metals is accompanied by large changes in their magnetic susceptibilities[1]. I suggested some preliminary ideas to the effect that the increased area of surface of the metal on colloidalisation might be responsible for the observed magnetic changes. Honda and Shimizu[2,3] have recently offered the more definite view that, in the case of tin, the lattice constant is somewhat larger at the surface layer than in the interior, and that consequently the paramagnetic component due to the free electrons decreases and the diamagnetic component due to the bound electrons increases, so that the colloidal powders become more diamagnetic than the massive metal. According to them, colloidalising a metal has the same effect as cold-working, so far as the magnetic properties are concerned.

Copper is a metal for which we have trustworthy magnetic measurements when cold-worked. Honda and Shimizu found that on reducing the density of the metal by cold-working, the diamagnetic susceptibility increased in value, after the necessary corrections were made for the presence of ferromagnetic impurities. A similar increase of the diamagnetic susceptibility was observed when metallic copper was colloidalised.

Colloidal copper was prepared by an electrical dispersion method[4], the dispersing medium being benzene or propyl alcohol. The dispersing and centrifuging experiments were conducted in the absence of air, and hence the possibility of chemical action modifying the results does not arise. It was found that the diamagnetic susceptibility (χ) of copper depended only on the dimensions of the particles and not on the nature of the dispersing medium. The magnetic measurements were made with a Curie balance, with water as the standard substance. Measurements were conducted at different field strengths to correct for the presence of ferrimagnetic impurities.

The specific diamagnetic susceptibility of copper in bulk was found[5] to be 0·080 (all values of χ are given in 10^{-6} units). As the size of the powders decreased from 10 μ to 0·8 μ, the value of χ showed a small increase from 0·080 to 0·090. When, however, the diameter was reduced from 0·8 μ to 0·4 μ, the value of χ showed a relatively larger change, from 0·090 to 0·135. These results fully agree with conclusions of Honda and Shimizu.

It will also be noted that the critical diameter below which χ increases rapidly is 0·8 μ, which is much smaller than the corresponding values for graphite (1·5 μ)[5], bismuth (1·4 μ)[6] and tin (2·0 μ)[1]. Since copper has a face centred cubic lattice, we have no directional variations as in the case of graphite or bismuth. It appears, therefore, most likely that the observed changes of χ in the case of copper colloids are to be attributed to causes quite different in nature from those arising in the crystals just mentioned.

An approximate calculation shows that the surface layer wherein the density is less than the density inside the metal is of the order of a few hundred atomic layers.

Full details will be published shortly elsewhere.

Oxide Film of Alloys containing Small Percentages of Aluminium

WHEN copper alloys containing more than 2 per cent aluminium were heated for many hours at a red heat (800°–900° C), no oxide scales were formed. In cases where several per cent of this element was added, the alloys even retained their characteristic golden yellow lustre, which is a very remarkable fact. Elements such as tin, zinc, nickel, manganese, magnesium, iron, etc., when added to copper do not produce this effect.

The oxidised surfaces were studied by means of cathode ray reflection. Copper surfaces exposed at a red heat gave the CuO pattern. (At lower temperatures, the Cu_2O and a three ring pattern were also observed, as first pointed out by G. P. Thomson and C. A. Murison[1].)

Upon heating alloys containing several per cent of aluminium at a red heat with a Bunsen burner, the surface in contact with air was blackened and gave the CuO pattern, while the surface imbedded in the oxidising flame remained bright and gave a pattern corresponding to that of pure γ-Al_2O_3. No diminution of the lustre of the latter surface was observable after continued heating.

The fact that alloys, containing only about 10 atomic per cent of aluminium, when heated with an insufficient supply of oxygen, become covered with a film of pure Al_2O_3 seems rather striking; because some copper oxide was anticipated. In the case where heating was done in air or in oxygen, the uppermost surface probably becomes covered with an extremely thin film of copper oxide, but beneath this layer, since oxygen is wanting, an Al_2O_3 film might be formed, and this in turn probably protects the inner part from further oxidation. Inasmuch as such a film is colourless, the alloy does not loose its golden lustre, even after prolonged exposure to red heat. The same may be true of iron alloys.

Iridium Isotopes and their Nuclear Spin

AN examination of the hyperfine structure of the arc lines of iridium λλ3800·10, 3513·67 and 2924·81 A. radiated from a modified form of hollow cathode reveals that the three lines having a common lower level in the ground term $5d^86s\ {}^4F_{4\frac{1}{2}}$[1] are identical in structure. The hyperfine components are therefore ascribed to a spin splitting of the ground term with the upper levels unsplit. λ3513·67 A. ($5d^86s\ {}^4F_{4\frac{1}{2}} - 5d^86p\ {}^4G^0_{4\frac{1}{2}}$) exhibits the following structure:

$d\nu$ in cm.$^{-1}$	(Int.)	Remarks
+ 0·072	(7)	This component is diffuse and appears almost as a continuous patch between
0·000	(22)	+ 0·072 and 0·000, indicating the
− 0·073	(13)	presence of an expected satellite at
− 0·145	(9)	+ 0·033 (9). (vide Fig. 1.)

The observed structure is accounted for uniquely by assuming two isotopes of masses 191 and 193 with nuclear spins of $\frac{1}{2}$ and $\frac{3}{2}$ respectively. The ratio of the magnetic moments of the two nuclei is nearly −1·0. The isotope displacement in $5d^86s\ {}^4F_{4\frac{1}{2}}$ is 0·057 cm.$^{-1}$, with the heavier isotope lying deeper, as in the arc lines of copper and thallium.[2] The incompletely resolved patterns of some other Ir I lines λλ3220·79, 2694·22, 2664·77 and 2639·70 A. support the above conclusions. The existence of isotope shift favours the suggestion that the ground term is a $^4F_{4\frac{1}{2}}$ term arising from an electron configuration $5s^25p^65d^86s$ in preference to a $^2D_{3/2}$ term from $5s^25p^65d^9$.[3]

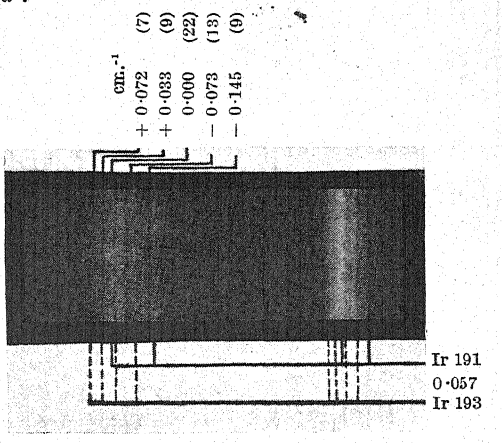

FIG. 1. Structure pattern of Ir I, 3513·67 A. obtained with a Hilger quartz Lummer plate, 3·45 mm. thick, 20 cm. long.

Iridium is one of the few elements the isotopic constitution of which has not so far been revealed by the mass-spectrograph. Judging from a visual estimate of the intensities of the components, the relative abundance of the isotopes 191 and 193 is 1 : 2, giving a value, perhaps a little too low, of 192·4 for the atomic weight of iridium. It appears, however, that the atomic weight of the iridium must be less than 193; there is considerable disagreement in the values of atomic weight given by several investigators, which range from 192·59 to 193·40. The existence of a heavier isotope like 195 is ruled out by the fact that usually there is no isobare in appreciable quantity for an isotope of an element with odd atomic number; and platinum has been previously shown to contain the isotope Pt 195 to the extent of nearly 30 per cent.[4]

Details will appear in the *Proceedings of the Indian Academy of Sciences*.

K-Series of Magnesium and Sodium

I HAVE already published[1] some results obtained in the region of long wave-lengths with the ionic tube designed and constructed by me with Prof. Dolejšek[2]. With this ionic tube and with a new focusing method, the principle of which will be described elsewhere, I have obtained some new results which show the great efficacy of our apparatus for long wave-lengths of X-spectra.

As an example of what can be obtained by our

ionic tube, I should like to point out in this connexion that with the ionic tube alone, using the normal Bragg method, I obtained the new non-diagram lines in the K-series of Mg and Al which were recently found by Prof. M. Siegbahn and H. Karlsson[3] using new focusing methods, which they have worked out. By our new focusing method and with this ionic tube I have obtained in the spectrum of Mg all these lines, and especially when nitrogen is let into this tube, I have further got, as can be

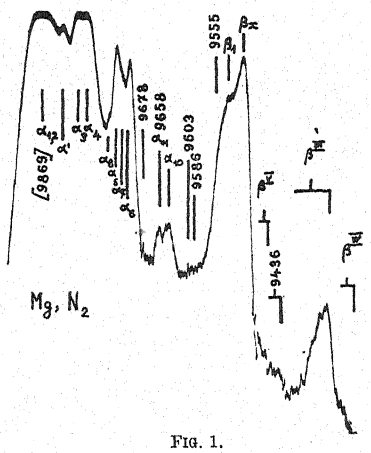

FIG. 1.

seen from the microphotometric curve (Fig. 1), the lines in the α-group as well as those in the β-group, which have not hitherto been observed.

In the emission spectrum of MgO, when oxygen is let into our ionic tube, there are certain changes; for example, in the α-group the lines 9603 and 9586 X. do not occur and $\alpha_{10,11}$ appear as a single broad band, and changes analogous to these also occur in the lines of β-group. I have found similar characteristic qualities in the spectrum of sodium

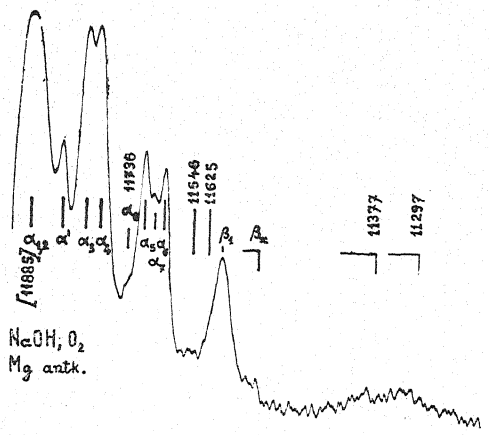

FIG. 2.

oxide. The microphotometrical curve of the spectrum of sodium (NaOH on the magnesium anticathode) is reproduced in Fig. 2. In these curves the lines which were hitherto neither known nor measured are indicated with their wave-lengths.

Both spectra were obtained using an effective tension of 2,000 v. and 200 ma. in the case of Mg, and 1,500 v. and 200 ma. in the case of Na, thus avoiding the occurrence of lines of higher orders.

As in the above investigation on the emission spectra of the K-series, I have tried to find the white absorption lines, which I have obtained while studying the M-series with the ionic tube and without the use of the focusing method. In the place where I formerly found two white lines and classified them as M_{II} absorption of Ta, I have now got these white lines and also obtained a complicated structure. But this absorption effect, classified by me as M_{II} absorption of Ta[4], must be classified as the absorption structure of sulphur from the crystal, which has not been observed until now. In the place where I formerly obtained the white line and classified it as M_I absorption of W, I have now again got the same line, and at present from our results it is not possible to find any other classification for it. It is necessary, however, to reinvestigate this identification since the results for both elements do not agree. This will be possible after obtaining more experimental data.

The examples mentioned of the results in the K-series and the absorption of sulphur show that our ionic tube, in connexion with any focusing method, gives further possibilities in the region of long wave-lengths.

Action of Benzylcarbonyl Chloride on Insulin and Other Proteins

IN previous investigations, the reaction between phenyl *iso*cyanate and proteins has been used to study the immunological properties of protein antigens[1]. In other investigations[2], it was found that insulin is readily inactivated by phenyl- and *p*-bromophenyl *iso*cyanates, and from the information derived from the earlier work, the conclusion was reached that this inactivation is due to a reaction between the *iso*cyanate and the free amino-groups of the insulin. Jensen and Evans simultaneously investigated this inactivation of insulin[3], and reached somewhat similar conclusions.

Recently, we have been studying the action on proteins of benzylcarbonyl chloride ($C_6H_5.CH_2.O.CO.Cl$), the reagent used with such success by Bergmann and his co-workers[4]. These chemical and immunological investigations are not yet complete, but sufficient evidence is available to show that this reagent reacts quite readily with native proteins, just as it does with the free amino-groups of amino-acids and simple peptides. This reaction, like that between phenyl *iso*cyanate and proteins, is quite mild, and proceeds smoothly at about *p*H 8 and 5° C. As the reaction continues, there is a marked diminution in the free amino-nitrogen of the protein, and in many cases, the product (benzylcarbonato-protein) contains practically no free amino-nitrogen. On injection into rabbits, the benzylcarbonato derivative of serum globulin produces antibodies which, from precipitin and inhibition tests, appear to be specific for the new grouping in the protein (the benzylcarbonato-amino acid group).

In the course of chemical and immunological investigations on insulin, the physiological activity of benzylcarbonato-insulin has been studied, and it has been found that this derivative has no significant

hypoglycæmic power. Benzylcarbonyl chloride readily inactivates insulin, probably just as rapidly as does phenyl *iso*cyanate, and in this inactivation also it seems probable that the loss of hypoglycæmic power by the insulin is due to the blocking of the free amino-groups. This appears to offer additional support for the view that the active groups of insulin contain free amino-groups, and that the latter are essential for the activity of the insulin (cf. Jensen[5]). Attempts are now being made to activate these inactive insulin derivatives.

The amount of benzylcarbonyl chloride required to inactivate insulin is very small, and 100 mgm. of insulin of potency 19,500 units per gm. (kindly supplied by Messrs. Boots Pure Drug Co., Ltd.), can be completely inactivated by 150 mgm. of this reagent. The minimum amount of benzylcarbonyl chloride needed to react with all the free amino-groups of insulin, calculated on the basis that insulin contains 1·0 per cent of free amino-nitrogen[6], is approximately 12 mgm. per 100 mgm. of insulin. This smaller amount of acid chloride causes partial loss of hypoglycæmic activity only, possibly because some of the reagent may be destroyed by the water present. It is possible, however, that the reaction with benzylcarbonyl chloride is not confined to the free amino-groups of the insulin, and further investigations are being made to decide this point.

Points from Foregoing Letters

SIR JAMES JEANS compares the observed eccentricity of the orbital motions of binary stars with that calculated from the principle of equipartition of energy. He points out that there is a good agreement between the calculated and observed figures, which supports the long time scale (10^{13} years) for the life of the universe.

To explain certain observations on blood group inheritance, Ffoulkes Edwards and Etherington have suggested the existence of a fourth hereditary unit (allelomorphic gene). Prof. J. B. S. Haldane points out, as one alternative explanation, that in some individuals the three known allelomorphs may be carried by three chromosomes, instead of by two, and he suggests ways of testing this hypothesis of 'trisomy'.

Prof. V. F. Lenzen offers a few remarks on the philosophical basis of science upon which, he hopes, all philosophers of science can agree.

Mr. A. E. Needham shows that Weldon's case of change of proportions in the growth of young shore crabs is due to heterogonic growth in the individual, and is not a mere average effect produced by natural selection.

The incidence of rickets in a new strain of 'rex-coated' rabbits (with mole-like fur) is described by W. King Wilson. Attempts to prove the recessive nature of the disease by mating individuals suffering from rickets were unsuccessful.

Vitamin C (ascorbic acid), in concentrations of 1 to 5 parts in 10,000, is found by László Havas to accelerate the growth and increase the length of the shoots of germinating wheat.

Prof. H. Munro Fox and Mr. H. G. Newth describe the swarming behaviour of two common species of gregarious vorticellids. All the individuals in a group become free-swimming simultaneously and form a swarm which is held together by mucous threads secreted by the swarmers. When the latter again settle down, they do so in close contiguity owing to their mucous attachments.

Prof. E. W. Scripture submits reproductions of sound-film tracks for various vowels. He points out that they support the 'puff and profile' theory, according to which vowel vibrations are produced by the action of glottal puffs on the air in the vocal cavity, and the perception of vowel characters depends on the unanalysed profiles of the vibrations.

Prof. S. Ramachandra Rao finds that the diamagnetic susceptibility of colloidal copper is greater than the value for the massive metal. The critical diameter of particles below which the susceptibility shows a rapid increase is 0·8 μ. The results support the conclusions of Honda and Shimizu that colloidalisation has the same effect as cold-working so far as the magnetic properties are concerned.

The protective effect of aluminium upon the oxidation of copper at red heat is described by I. Iitaka and S. Miyake, who have studied the oxidised surfaces by means of cathode ray reflection. Copper alloys containing more than 2 per cent of aluminium can be heated to a red heat for several hours without forming oxide scales. An alloy containing about 10 per cent, when heated with an insufficient supply of oxygen, becomes covered with a thin film of oxide.

From the hyperfine structure of certain lines of the arc spectrum of iridium—the only element the isotopes of which have not hitherto been identified—Prof. B. Venkatesachar and L. Sibaiya infer the existence of two isotopes of masses 191 and 193 with nuclear spins of $\frac{1}{2}$ and 3/2 respectively. A rough estimate of the relative abundance of the two isotopes is 1 : 2, which in the absence of a higher isotope would lead to an atomic weight of less than 193 for iridium.

By means of the ionic tube designed by Kunzl and Dolejšek, for the detection of the longer X-ray waves and with a new focusing method, Dr. V. Kunzl has observed several new lines in the X-ray spectra of magnesium and sodium. He now ascribes to sulphur certain 'white lines' previously classified as due to the absorption spectrum of tantalum.

The observation that Bergmann's reagent (benzylcarbonyl chloride) inactivates insulin is considered by W. E. Gaunt, G. Higgins and Dr. A. Wormall as additional support for the view that the free amino-groups of insulin are essential to that compound's power of reducing the sugar content of the blood.

Research Items

Glazed Stones

In continued study of glazed stones, Mr. H. L. Beck deals with glazed quartz and carnelian, agate and felspar (*Ancient Egypt and the East*, Pt. 1, 1935). In the glazing of quartz (including quartzite and chert), great care has to be taken to prevent flawing of the quartz base. The glazing of quartz was practised in Egypt from Predynastic times to the eighteenth dynasty. In Mesopotamia, beads are found at different dates in two varieties, *high polish* and *frosted*, so called on account of the present surface. Some at Ur are dated from before 3500 B.C., though some of A.D. 900 are identical. Beads are also found in Persia and Syria. Three of the high polish variety were found at Mohenjo-daro, one, a lenticular cylinder, being of a shape not recorded in either Mesopotamia or Egypt. A number of specimens of glazed quartz have been found in northern India, which are dated at the first century A.D. No specimens are reported from Europe; and the process is not practised to-day. The great majority of specimens of glazed quartz from Egypt are beads. In India there is a number of small but elaborately worked pendants representing animals. In Egypt a soda glaze coloured was applied to the bead and then fused. The Mesopotamian coloured beads were hammered to cover them with conchoidal fractures before glazing. In the high polish beads the surface is altered by an alkali. It is possible that all types were coloured. The most important other stones chemically treated were carnelian, agates and chalcedonies. They were not actually glazed, but received a special treatment in which soda was added, usually as a decoration. Many carnelian beads have a white patination; but it is difficult to say whether it has been purposely applied or is due to action of the soil.

Kmer Art and the Cultures of Precolumbian America

M. Henri Marchal offers (*J. Soc. Américanistes*, N.S., **26**, 2) a tentative explanation of certain remarkable features in Kmer art, which appear out of harmony with its Indian origin and its relation through the art of India with that of ancient Egypt, Greece and the Mediterranean. These incongruous elements are to be attributed to the Polynesian influences which have been discerned in the art of Java and Bali, and also in America. As an example may be taken the monstrous heads, known in Cambodia as *Rahu*, which with the *naga* form one of the dominant motifs in Kmer art. The characteristic lineaments appear nowhere in occidental art (except in the head of Medusa and its derivatives) but are to be found in the Mayan art of America, especially in the heads placed over the openings into buildings, for example, at Palenque, exactly as they are used in Cambodia and Java. They are to be found also on Toltec pottery, where the god Tlaloc is represented without lower jaw. This motif is scattered widely over Polynesia, appearing in Maori art, especially in the carved wooden lintels and gables of New Zealand, and the tattoo-markings and petroglyphs of the Marquesas. The head with flanking forearms or claws of America does not appear in Polynesia, but is present in China. Superimposed heads forming balusters before the entrance to Kmer temples may be compared with sculptured figures of Piedras Negras in Central America. A striking resemblance which has impressed everyone who has visited both localities is to be found in the general profile of the *teocallis* or pyramidal mounds of America and the *prasat* of Cambodia. Step pyramids surmounted by sanctuaries in Mayan architecture find their analogies in Kmer temples such as Phimānakas, Bakon and above all the Pran of Kohker. Among other resemblances in construction are the introduction of a wooden beam in masonry work, the projecting stone which is carved, the use of the serpent for decorative purposes, and the employment of the corbelled arch.

Fishes from the Philippine Islands

The *Philippine Journal of Science*, **55**, No. 3, 1934, contains three papers on fishes: (1) "The Philippine Phallostethidae, a Description of a New Species, and a Report on the Biology of *Gulaphallus mirabilis*, Herre" by D. V. Villadolid and P. R. Manacop; (2) "Philippine Sillaginidae" by M. C. and H. R. Montalban; and (3) a long systematic paper on Philippine Isospondylous fishes by A. H. Roxas. The Philippine Phallostethidae comprise a very interesting group of fishes, unique in having a peculiar sexual organ in the male, named the priapium by Tate Regan, who first discovered it in 1913. The pelvic fins are vestigial in the female and absent in the male, the latter having below the head and throat this priapium containing the coiled vas deferens and the end of the intestine, together with a complicated skeletal system consisting of two long curved bones, proved in the present paper to be used as a clasping organ. The eggs are probably fertilised as they pass through the oviduct, and when laid are provided with adhesive thread-like processes with which they attach themselves to weeds. These filaments seem to suggest that the genus is more closely related to Percesoces than to the Cyprinodontes where they are usually placed. Spawning appears to continue throughout the year. Interesting notes on food and feeding habits are added, *Gulaphallus* having a mixed diet both in young and adult consisting of vegetable matter which is less as the animal grows, insects, especially chironomid larvæ and pupæ, which rank first in importance, small crustacea and even the larvæ of its own species, eaten by both young and old but only in January when the breeding season is at its height. The development of *Gulaphallus mirabilis* is described from the newly hatched egg to the time when the priapium is fully formed—in about 19–20 weeks after hatching.

Germ-Cell Cycle in the Hessian Fly

Margot E. Metcalfe (*Quart. J. Micr. Sci.*, **77**, Pt. IV; 1935) has investigated the germ-cell cycle in the Hessian fly, *Phytophaga destructor*. The somatic cells in both sexes contain four pairs of V-shaped chromosomes. The germ-cells in both sexes contain eight pairs of chromosomes. In the maturation of the egg, eight bivalents are formed, which divide but remain in anaphase until the time of fertilisation.

The polar bodies are then formed, but are never extruded from the egg; they migrate to the surface of the egg, divide irregularly and eventually degenerate. The female pronucleus has eight chromosomes. In spermatogenesis, reduction is effected in a peculiar manner. In the first spermatocyte the chromosomes separate into two groups, of twelve and four respectively, and the four pass into a process of the cell which separates as a small cell. After a short period of rest, the spermatocyte again divides unequally, the resulting spermatid having eight chromosomes and the second bud four chromosomes. Thus each spermatocyte gives rise to one sperm only. The germ-line (that is, the germ-cell nucleus). is differentiated after the third cleavage, that is, in the eight-cell stage. At the fourth cleavage the germ-cell nucleus divides synchronously with the somatic nuclei; there are sixteen nuclei each with sixteen chromosomes. At the fifth cleavage the somatic nuclei eliminate eight chromosomes and are left with eight chromosomes.

Hystricoid Rodents of the Neotropical Region

A VALUABLE, if necessarily dull, account of the taxonomy of these rodents has appeared (*Bull. Amer. Mus. Nat. Hist.*, **68**, Art. 5; 1935). The author, G. H. H. Tate, gives fully for each genus its pre-Linnean and post-Linnean taxonomic history, discusses special points of difficulty, indicates the genotypes, and gives a list of all the named forms, specific and sub-specific, with their type localities.

New Garden Alpine Plants

NUMEROUS expeditions to Persia, Tibet, Burma, the Andes and other places have recently been organised for the purpose of collecting new plants for the enhancement of garden beauty. The names of Farrer, Kingdon Ward, Giuseppi, Comber, Ball and others are well known among gardeners for their activities in botanical exploration, and modern gardens owe much of their interest to them. An article by Dr. H. R. Smith on "New Alpines" (*J. Roy. Hort. Soc.*, **60**, Part 6, pp. 246–255, June, 1935) enumerates an imposing list of plants for the rock garden which have been introduced during the last five years as a result of such botanical exploration. Lilies and rhododendrons are not treated, but more than sixty species belonging to other genera are described. Campanulas, primulas, gentians and narcissi are well represented, and brief accounts of the circumstances of their introduction are given.

Life-Histories of British Pyrenomycetes

MR. C. G. C. CHESTERS has commenced a series of studies on British Pyrenomycetes. The whole life-histories of most members of this division of the fungi are not known, and many phases probably lie buried among the taxonomic labyrinths of the Fungi Imperfecti. Pure culture methods are used in the investigation, and the first part of the work is devoted to "The Life-Histories of Three Species of Cephalotheca" (*Trans. Brit. Mycol. Soc.*, **19**, Part 4, June 1935). The three species which have been recognised are *C. sulfurea*, *C. purpurea* and *C. reniformis*. These are described in minute detail, and characters of the genus are also given. Extensive lists of synonyms appear, and the mass of detail portrayed in the paper is crystallised into a very simple determinative key at the end.

The Formosa and Quetta Earthquakes

A PRELIMINARY report on the Formosa earthquake of April 21, by Mr. R. Takahasi, is published in the *Proceedings of the Tokyo Imperial Academy* (**11**, 224–226; 1935). The number of lives lost was 3,276, and that of the houses completely destroyed 121,398, this great number being due to the poor construction of the houses. Displacements occurred along several faults during the earthquake. Along one, more than six miles in length, the horizontal and vertical displacements were respectively 6 in. and 2 in. Along another, a thrust fault of about the same length, the horizontal movement was slight, but the vertical shift amounted to 10–12 in. The epicentre lay in about lat. 24° 22′ N., long. 120° 48′ E., or between the two above faults. The detailed report will appear later in a special volume of the *Bulletin of the Earthquake Research Institute*. In a paper in *Science and Culture* (**1**, 71–72; 1935), Messrs. S. N. Sen and R. Bakshi determine the epicentre of the Quetta earthquake of May 31 as in about lat. 30½° N., long. 66½° E., or along the Khojak Range just to the south of Chaman and about sixty miles north-west of Quetta. Thus, the origin of the recent earthquake coincides closely with that of the severe earthquake of December 20, 1892, caused by a large displacement along the boundary fault which has been traced for a distance of 120 miles.

Thermodynamical Relations

PART NO. 740 of vol. 234 of the *Philosophical Transactions of the Royal Society*, A, is devoted to a communication by Prof. A. Norman Shaw of McGill University on "The Derivation of Thermodynamical Relations for a Simple System". The aim of the author is to outline a systematic procedure for effecting transformations of thermodynamical formulæ which involve quantities not directly determined by experiment or determined with low accuracy, in order to replace them by quantities directly observed or determined with higher accuracy. The method adopted is that of converting any thermodynamical equation involving the usual quantities p, v, T, S, E, I, F and G and their derivatives with respect to each other into an equation connecting Jacobians of the partial derivatives of two quantities x and y with respect to two independent variables α, β by assigning to x, y, α, β values identical with any number up to four of the above thermodynamical quantities. Thus the thermodynamical equation $dE = TdS - pdv$ is converted into $J(xE) = TJ(xS) - pJ(xv)$ where J is the symbol for Jacobian and x and the independent variables α and β are undetermined. Once the equations are in Jacobian form the laws of transformation of Jacobians can be utilised to effect the thermodynamical transformations required. To facilitate the work four tables are given in which x, y, α, β are assigned values p, v, T, etc., and the resulting Jacobian expression tabulated in terms of five of the simplest Jacobians. Instructions for the use of the tables and worked examples are given as well as 35 equations useful in manipulations of J functions.

The Electronic Oscillator

CONSIDERABLE research has been carried out recently on the generation of electrical oscillations corresponding to wave-lengths of 10–100 cm., by means of the valve circuit arrangements first demonstrated by Barkhausen and Kurz. The

theoretical study of this subject has resulted in the publication of much complicated analytical work, the physical principles of which have at times been somewhat difficult to visualise. The author of some of this theoretical treatment, Mr. F. B. Llewellyn, has presented a simple statement of these principles in plain language in an article entitled "The Barkhausen Oscillator" published in the August issue of the *Bell Laboratories Record*. The case considered is that of a simple triode valve operating with a positive grid potential; and the oscillating motion of individual electrons between cathode and anode through the spaces of the grid is dealt with. The difference in motion of these electrons due to the static forces alone and with the superimposition of the alternating forces due to the potential difference across the external tuned circuit is explained and illustrated graphically. The maintenance of oscillations is shown to be due to the non-symmetrical motion about the grid of those electrons which are correctly phased relatively to the alternating forces, and the consequent transfer of some of their energy into the external tuned circuit. The tuning of this circuit can modify the frequency of the oscillations by about thirty per cent, but for fixed supply voltages of the valve electrodes, there is a particular tuning adjustment which gives maximum output.

Platinum Electrode in Solutions of Foreign Ions

MR. I. ORESTOV, of the Middle Asiatic State University, Tashkent, informs us that he has studied the behaviour of a platinum wire electrode in a series of solutions of potassium sulphate of normalities 0·5005, 0·1001, 0·0500 and 0·0100, with a salt bridge and saturated calomel electrode:

$$Pt|K_2SO_4(c)|KNO_3(sat.)|KCl(sat.)|Hg_2Cl_2|Hg$$

and very variable potentials were found. When, however, a stream of pure nitrogen was passed through the left-hand half element, a reading taken after 90 minutes showed that all four electrodes had on the average the same potential of $0{\cdot}2336 \pm 0{\cdot}0010$ volt. Observations with one electrode (N K_2SO_4) at 23·1° were then made every minute and 90 readings obtained. These were arranged in a statistical row which was found to correspond very closely with the natural theoretical row, the standard deviation σ being $\pm 2{\cdot}35$ mv., the index of closeness of fit (Pearson) being $\Delta = \pm 2{\cdot}33$, the asymmetry number S being $+ 0{\cdot}23$, and the excess $Ex = + 0{\cdot}2$. The source of the fluctuations, following a suggestion of Posner, is regarded as the fluctuations of ions in a Helmholtz double layer on the electrode. Further observations are in progress, when the theory of fluctuations (Smoluchovsky-Svedberg) will be applied to the results.

Probability and Frequency

A SATISFACTORY basis for the theory of probability has not yet been found. The weakness of the 'equally-likely' definition is well known, but the 'statistical' or 'relative frequency' definition, favoured by Chrystal and others, is also open to objection. An interesting discussion of some of the fundamental difficulties has been given recently by F. P. Cantelli (*Ann. l'Institut Henri Poincaré*, 5, 3; 1935). If a symmetrical coin, equally likely to turn up head or tail, is tossed a large number of times, it is not certain that the proportion of heads will be exactly $\frac{1}{2}$. What is more, it is not even certain that the proportion will approach $\frac{1}{2}$ as a limit; for if it were, to any number ε, however small, there would correspond a number N such that for every set of N or more tosses the proportion of heads would *never* differ from $\frac{1}{2}$ by more than ε. But this is not true; long runs of heads or of tails are not impossible, a fact which is awkward for mathematicians as well as for gamblers. The statement of the approach to the limit must be weakened, with *never* replaced by *scarcely ever*. The principal object of Cantelli's work is to express this replacement in precise mathematical terms drawn from the theory of aggregates.

Molecular Weights by the Ultra-Centrifuge

THE most satisfactory method for the determination of the molecular weights of macromolecules is by means of sedimentation equilibrium in the Svedberg ultra-centrifuge. The equations can be developed by thermodynamics, so that for sufficiently dilute solutions the shape of the molecule is not involved. In the case of material containing molecules of different sizes, average molecular weights are obtained. It is then necessary, for purposes of comparison with values found by other methods, such as viscosity determinations, as used by Staudinger, to have properly defined averages, and W. D. Lansing and E. O. Kraemer (*J. Amer. Chem. Soc.*, 57, 1369; 1935) have distinguished three such averages. The first, the number average, M_n, corresponds with osmotic methods involving counting of the molecules; the second, the weight average, M_w, corresponds with Staudinger's method, and a third, the so-called 'Z-average' molecular weight, M_z, is obtained from centrifuge data. The concentration of a solution subjected to a centrifugal or gravitational field is such that the concentration gradient at equilibrium ensures that at every point the chemical potential is equal but opposite in sign to the gravitational potential. Equations can then be set up giving the molecular weight from the experimentally observed concentration gradient. If this value varies with the distance along the cell, the material is assumed to be non-homogeneous. The authors enter into a detailed discussion of the calculation of the average molecular weights and apply the results to experiments on gelatin. The equations enable a correct comparison to be made between results obtained by different methods, thus avoiding a good deal of confusion which has hitherto resulted in this field.

Distance of Nova Herculis

THE majority of novæ are so far away that accurate measurements of their distances are very difficult to obtain. Trigonometrical parallaxes are too small to be trustworthy, and the best method so far depends on the rate of expansion (when available) of the surrounding nebular disc. An entirely independent method is now possible through the relation between distance and interstellar calcium absorption. This has been used in the case of Nova Herculis by E. G. Williams (*Monthly Notices, R.A.S.*, 95, 573), who has measured the intensity of the interstellar [*K*] line on twenty-four plates taken at Cambridge. The large displacements of lines due to the Nova itself, together with the absence of lines which might blend with the interstellar line, make these measurements comparatively simple. They yield a distance of 370 parsecs for Nova Herculis, corresponding to an absolute magnitude at maximum of $- 6{\cdot}5$ and a pre-outburst magnitude of about $+ 6{\cdot}7$.

International Society of Leather Trades' Chemists

THE bi-annual Conference of the International Society of Leather Trades' Chemists was held at the Institut des Arts et Métiers, Brussels, on September 1–6, jointly with the bi-annual meeting of the German sister society, the Internationalen Vereins der Leder Industrie Chemiker. Owing to the national mourning for Queen Astrid, some of the social functions in connexion with the Conference were cancelled. The meeting, however, was pronounced as one of the most successful yet held.

The Conference proper opened on Monday, September 2, under the chairmanship of M. G. Colchen (president of the Belgian Section, I.S.L.T.C.), assisted by Mr. Van Gijn (president of the I.V.L.I.C.) and M. C. R. Loos (president of the I.S.L.T.C.).

The Executive of the I.S.L.T.C. for 1936–37 was elected as follows: *President*, M. G. Colchen (Belgium); *Vice-Presidents*, M. C. R. Loos (France) and W. R. Atkin (University, Leeds); *Treasurer*, Prof. D. McCandlish (University, Leeds); *Hon. Gen. Secretary*, Dr. J. Gordon Parker (London); *Members of Committee*, Dr. P. Chambard (France), Dr. A. Gansser (Italy), M. R. Paniker (Spain) and L. Masner (Czechoslovakia). It was decided to hold the 1937 conference at Copenhagen. Dr. J. Gordon Parker was elected an honorary member of the Society in appreciation of the enormous amount of work he has devoted to its welfare. The official methods of analysis of the Society are to be published in book form, and it is hoped to have the publication ready by the end of the year.

Kubelka, Weinberger and Heger showed that acid rotting of vegetable tanned leather can be detected by extracting the sample first with water and then with 1 per cent caustic soda solution, and determining the nitrogen in the extracts, rotting being indicated by unusually high amounts of soluble nitrogen. Kubelka and Nemec demonstrated that the deposition of tannin sludge from a liquor depends upon concentration, the sludge increasing with concentration up to a maximum, and then on further concentration decreasing in quantity. In discussing the effect of metallic iron on vegetable tanned leather, Kubelka, Nemec and Zuravlev stated that the presence of unsaturated and oxy fatty acids in oils used for dressing resulted in a greater uptake of iron than with saturated acids such as stearic acid or neutral greases such as paraffin wax.

Dr. D. Jordan Lloyd discussed the modern theories of tanning, stating that X-ray examinations of collagen and of good quality and poor quality sole leathers show that tanning occurs at the active centres of the side chains of the collagen molecules and influences the side chain spaces of the bundles of parallel molecules that go to build up the collagen fibril (or fibre). If the tanning processes weaken or affect the collateral forces directly binding the backbones of the bundles of collagen molecules, or the longitudinal forces down the backbones of the molecules, the leather is of poor quality. All these inter- and intra-molecular forces can of course be affected by the pre-tanning processes, such as those which have been used for curing and in beamhouse work.

The influence of the hydrogen ion concentration of suspender tanning liquors on the fixation of tannin was the subject of a paper by G. Rezabek. He showed that at *p*H 4, hide powder fixes about one sixth to one quarter more tannin than at the natural *p*H of the liquors, namely 5 or 6. Tannage in alkaline medium, that is, at *p*H 8, gives approximately the same tannin fixation as in the non-adjusted liquors. The value of the microscope was illustrated by Dr. R. H. Marriott, who emphasised the value of an understanding of the fibre structure of leathers when assessing their value. Apart from its use in examining finished leather, microscopical examination is of the utmost value in detecting faults in the early manufacturing processes.

Dr. A. Jamet described a method for the estimation of formic acid in lactic acid based on distillation in the presence of a definite amount of lactic acid, whereby the formic acid can be recovered almost quantitatively. Dr. V. Casaburi and Dr. E. Simoncini discussed tanning by means of tungsten salts, particularly those of a more complex type. These tungsten compounds also act as excellent mordants for dyeing. A study on the action of nitrous acid on collagen, and the properties of the de-aminated collagen, was presented by Prof. L. Meunier and Dr. E. Schweikert. An excess of nitrous acid results in a true tanning effect, particularly if followed by treatment with sodium bisulphite. Further, at the iso-electric point of collagen, sodium nitrite alone has a marked tanning effect on collagen. The action of acids and basic dyestuffs towards deaminated collagen were described in some detail. Prof. C. Otin and G. Alexa gave an account of their work on the fixation of vegetable tannins by pre-chromed hide powder, indicating that the amount of vegetable tannin fixed depends upon the quantity of chromium present, also on the particular vegetable tannin used.

Some work on the accuracy of the glass electrode in alkaline solutions was discussed by Dr. D. Burton and J. Bateson. Prof. L. Meunier with A. Abbassi showed that a sulphur tannage takes place when pelt is treated with an acid pickle (salt and sulphuric acid) followed by a sodium thiosulphate bath. A very practical paper was that by L. Houben, who demonstrated the important part played by the stuffing grease mixture on the efficiency of leather belting. Prof. L. Meunier with P. Audrey described a method for preparing a uniform ossein from bones, and showed that this can be used as a substitute for hide powder in the determination of tannin in vegetable tanning materials. The estimation of methoxy (in the form methyl alcohol) in vegetable tannin extracts is the basis of a method for determining the presence of sulphite cellulose described by C. van der Hoeven.

In a paper on the theory of leather dyeing, Dr. G. Otto suggested that in dyeing with anionic reacting dyestuffs, the reaction of the principal valencies is more or less influenced by auxiliary valencies. Dr. F. Stather described experiments he has made on the relative rates of diffusion of vegetable tannins into pelt. Dr. Pollak gave details of his method for determining pyrogallol tannins in the presence of catechol tannin, the latter being precipitated by formaldehyde and hydrochloric acid (Stiasny), and then the former by urea. Sulphite cellulose extract

formed the subject of a paper by Dr. Kuntzel, who showed that this material is taken up by the basic groups of the hide substance molecule, and acts generally like the synthetic tannins.

A conclusion arrived at in a paper by Dr. E. Elod on the dyeing of leather is that if a series of acid or direct dyes be arranged in order of their dissociation constants, such order represents also their relative fastness to washing. The importance of drying in leather manufacture was discussed by Dr. K. Wolf, who mentioned that drying occurs in two stages, first the evaporation of the loosely held water, and secondly the loss of bound water, this latter being governed by the type of tannage and degree of tannage of the leather. Dr. W. Grassmann dealt with the chromatographic adsorption analysis of tanning materials. This depends on passing the solution through a tube of an adsorbent material (silica gel, kaolin, etc.) when a characteristic separation occurs, the strongly adsorbed constituents being retained in the upper layers while other constituents infiltrate to various depths. The preparation of sulphite cellulose extracts was discussed by L. Masner and V. Samec, and Dr. W. Hausam described certain pin hole defects in calf and goatskin.

Prof. Leplat gave an interesting lecture on the need for closer co-operation between the histologist and leather technologist, and showed how the newer science of histo-chemistry has been able to differentiate structural differences between tendon fibre and skin substance, which may account for their different behaviour on acid swelling.

Higher Agricultural Education in Great Britain

THE Report of the Departmental Committee on the Reassessment of Annual Grants to Institutions providing Higher Agricultural (excluding Veterinary) Education in England and Wales, 1934, is regarded by the Minister of Agriculture as of such importance that the non-confidential portions have been reproduced in full in the *Journal of the Ministry of Agriculture* of August 1935. It is understood, however, that some of the recommendations have already been implemented.

The fifteen institutions concerned, comprising agricultural colleges and university departments of agriculture, were visited by members of the Committee, and all available information as to work and finances considered in detail. The Committee lays great stress on the importance of education and research for the development of agriculture, quoting many specific instances where the results of research have materially altered the methods of agricultural practice. The importance of the agricultural colleges lies in the fact that experience shows that the farmers who are the first to introduce improved methods on their own farms and, indirectly, to their neighbours, are those who have received training at a college or farm institute. Any attempt to reorganise the agricultural industry in Great Britain must, therefore, ensure that the agricultural colleges are on such a footing that they can perform their functions with efficiency.

The attitude of the Committee was sympathetic and liberal, the object being to make such recommendations as would ensure the financial stability of each institution, without countenancing any waste or unnecessary expenditure of public money. At the same time, it was agreed that it is a mistake to penalise an institution that is successful, and that one that is so well managed that it pays its way should not on that account alone suffer a reduction in its grant. The financial crisis of 1931 prevented any increases in grants, and caused reductions in many cases, and as lowered incomes from this and other sources mean reduced expenditure, the position of the colleges in 1934 was one of stagnation due to lack of funds, rendering them unable to play their full part in the leadership of the agricultural industry.

Most of the colleges work in direct relation to the surrounding county areas; but the amount of local financial support varies considerably, both as regards direct grants and the award of scholarships, and in some cases this support is far from adequate. An increase in both types of financial aid from certain counties is very desirable, together with a greater co-operation for making the facilities provided by the colleges more widely known.

In most cases the existing staff is adequate to meet present demands, but the level of the salaries paid leaves much to be desired. This, added to the salary cut imposed in 1931, has resulted in deplorable conditions in certain specified colleges, and recommendations have been made for extra grants to improve conditions.

One result of the 1931 depression has been a fall in the number of fee-paying students, with a certain increase in scholarship holders, and in some cases the quality of the students is less good than formerly. It is recommended that the colleges should be pressed to satisfy themselves that all their students are suitably equipped to benefit by their course of instruction, and that a more rigorous attitude should be adopted in the weeding-out of students who are not availing themselves of their opportunities. At the same time, it is desirable that every effort should be made to increase the numbers of students drawn directly from agricultural circles, which can be encouraged by scholarships given by the Ministry and by county authorities. There seems to be scope for a much greater measure of county assistance in this respect.

The attention of the Committee was also directed to the question of adequate farm areas attached to the colleges. Although most colleges already possess such farms, in some cases they might be used more freely for the practical instruction of the students. For urban colleges, the distance to the farm may present difficulty, and in one instance the establishment of a local farm institute on the farm itself has been recommended as the condition of the continuance of the existing grant.

In spite of the reduced incomes, due to various causes, it is most undesirable that any increase in the level of fees paid by students should be made, as even now the cost is too heavy for members of the agricultural classes without the aid of scholarships or reduced fees. The heavy burdens of interest charges and bank overdrafts could best be dealt with

by increases of grant sufficient for their gradual reduction. Considerable items of capital expenditure still call for the Ministry's contribution on a pound for pound basis; but if possible, smaller items should be met out of a margin provided by an adequate annual grant.

As a measure of security for the proper use of the suggested increased grants, the report proposes that annual visits should be paid to colleges and farms by responsible officials and technical officers of the Ministry. It also recommends that members of the county committees should periodically visit any college to which a grant is made, with the view of increasing the co-operation between colleges and counties.

If the suggestions outlined above are put into force, the position of the agricultural colleges of Great Britain will be greatly strengthened, and they will be enabled to make a much greater contribution towards improving agricultural practice throughout the country.

International Longitude Operations

THE Observatory of Zi-Ka-Wei, which took part in the International Programme of Longitude Operations in October and November 1933, in addition to transmitting its results to the Commission of the International Astronomical Union responsible for the general reduction of the whole work, has published its own observations in its *Annales* (t. 20).

The Observatory kept its own time with two pendulums, Leroy 1227 and 1338, working at constant pressure and a temperature controlled by a thermostat. Meridian observations were made with two transit instruments, the Zi-Ka-Wei instrument used in 1926 and a similar instrument which was brought from Nice by M. Fayet. Observations with both instruments were secured on twenty-eight nights by four observers, each of whom used both instruments. The maximum difference between the clock errors deduced from the two instruments on the same night was $0{\cdot}04^s$, and the difference was generally less than $0{\cdot}02^s$. Wireless time signals were received from a number of stations, including DFY (Nauen) and FYL (Bordeaux). Time lags in the reception of the wireless signals were determined by a method due to M. Jouast, and it is hoped that their effect has been eliminated. The longitude of Zi-Ka-Wei minus Paris is found to be $7^h\ 56^m\ 21{\cdot}962^s$ in 1933, as compared with $21{\cdot}975^s$ in 1926. The difference between the two determinations is thus $0{\cdot}013^s$ (the equivalent of 17 ft. on the earth's surface) which is presumably scarcely outside the limit of accidental error; but it is of interest from the point of view of continental drift to note that observations of this kind would certainly have shown up a drift of seventy feet on the earth's surface during the seven years that elapsed between the two determinations. It is certain that the reality or otherwise of continental drift will be settled by these precise longitude observations, when a long enough time interval has elapsed.

The director of the Zi-Ka-Wei Observatory directs attention to a puzzling periodic variation from the mean longitude with an amplitude of $0{\cdot}05^s$ and period of one month. This is shown by the 1933 observations as well as by those made in 1926. He concludes that it is not possible to incriminate either the meridian observations or the reception of the time signals, and is inclined to attribute these fluctuations to a periodic deformation of the earth's crust. One is reminded of a somewhat similar effect in the longitude difference Washington minus Greenwich, which has been pointed out by Loomis and Stetson. The precise nature of the cause of this variation is obscure.

Biology and Variation of *Ceratium*

THE introductory report* (No. 1) to the Carlsberg Foundation's Oceanographical Expedition contains an article in memory of its late leader, Prof. Johannes Schmidt, by Martin Knudsen, with portrait, a foreword by P. Jespersen and Å. Vedel Tåning, a list of stations and, finally, the results with detailed tables of the echo-soundings, with introductory remarks by Sv. Greve. There are also seven maps showing the stations.

This was the last and the greatest of the many expeditions in which Schmidt personally took part, from June 14, 1928, until June 30, 1930. Like all those which he conducted, it was planned and conceived in every detail by himself. He took care that the investigations were as many-sided as possible, and maintained his interest in discovering connexions between the biological and physico-oceanographical conditions. The principal features in the biological-zoogeographical methods of work and the plans for the Expedition were drawn up by him in the following summary:—

(1) With the aid of the most efficient apparatus to obtain a very large material, rich in individuals, of the pelagic life in the different depths and the various oceans.

(2) With the aid of simultaneous, methodical investigations on the physical and chemical composition of the different water layers, to obtain data which would permit us to conclude under what environmental conditions each single one of the millions of pelagic organisms, taken in the nets, may live.

* The Carlsberg Foundation's Oceanographical Expedition round the World 1928–30 and Previous *Dana* Expeditions under the Leadership of the late Prof. Johannes Schmidt. Dana-Report No. 1. Introduction to the Reports from the Carlsberg Foundation's Oceanographical Expedition round the World 1928–30. Pp. 130+7 plates. 16*s*. net. No. 4. Untersuchungen über die Verbreitung, Biologie und Variation der Ceratien im südliches stillen Ocean, von E. Steemann Nielsen. Pp. 67. 8*s*. net. (Copenhagen: C. A. Reitzel's Forlag. London: Oxford University Press, 1934.)

(3) By means of the large pelagic material to subject a number of important oceanic species or genera to a finer analysis, with reference to classification, than has previously been possible with the frequently somewhat scanty material available from the distant waters.

The Expedition was successful in every way, and the results of the investigations now being published show its extreme value. It is to be regretted deeply that Schmidt did not live to see more of the fruits of his carefully planned work. The reports now being published are to appear in parts. No. 2 (Deep-Sea Angler Fishes (Ceratioidea)), by C. Tate Regan and Ethelwyn Trewavas, was published in 1932. Dr. Nielsen, who took part in the Expedition, now contributes an important monograph (No. 4) on the Ceratia in the southern Pacific Ocean. The genus is taken as representative of the phytoplankton and the whole work touches on many vital problems.

The *Ceratium* material is from two Danish Expeditions of the steamer *Dana*. In January 1922 in the Gulf of Panama and in September 1928–March 1929 on the present Expedition, through the Pacific Ocean from Panama to New Zealand–Australia, 68 stations were sampled, and in all the oceanic stations the Nansen closing net was used. Whilst on the first Expedition samples were taken at other depths, in 1928–29 the catches were almost wholly made at the depths 200–100 metres, 100–50 metres, 50–0 metres. The surface net was only used at shallow coastal stations where a vertical separation of species of *Ceratium* would be unimportant. Sixty species were recognised besides several sub-species and variations.

The larger part of these *Ceratium* species are oceanic, but a few are typically inhabitants of coastal waters, that is, neritic. The author's main conclusions are that temperature, currents and oceanic-neritic waters are the chief factors influencing the horizontal distribution of the *Ceratia*, the variation in the species depending on the first and the last. He finds that a rising temperature tends to lessen the size of the cell, and, in some species, there is a lengthening of the horns at the same time. Under a neritic influence the cells are usually large and there is almost always a lengthening of the horns. The case of *Ceratium fusus* is striking, for in neritic waters it is nearly double the size of that in purely oceanic conditions. The cause of this large size is evidently not the better nourishment of the cell, since the *Ceratium* population in the eutrophic east equatorial stream where the neritic influence is much felt are no greater than in the oligotrophic oceanic stations with the same surface temperature. The author is of the opinion that the dearth of *Ceratium* species in purely neritic waters compared with the large numbers in the oceanic stations is to be attributed to the accumulation of the waste products from the breaking down of the many organisms in neritic regions where the water is only renewed very slowly, these substances being usually poisonous to the sensitive oceanic species.

There is a striking agreement of the *Ceratium* populations in the Pacific and Atlantic Oceans, few species being peculiar to one or the other.

It is shown that the genus has a very characteristic depth distribution. About a third of those found in the Pacific are so-called 'shadow' species. In the plankton-poor water these were found chiefly in the samples below 50 metres, whilst most of those where the plankton was rich were chiefly above this depth. The 'shadow' species are all oceanic. They require only a moderate light intensity, but in those waters where there is abundance of plankton this moderate light intensity is nearer the surface. All *Ceratium* species which have a very broad flattened body or in some other way have the assimilation surface enlarged are 'shadow' species. In those regions where they live, the nutrient salts are always considerable.

Genetics at Cold Spring Harbor, N.Y.

THE latest annual report of Dr. C. B. Davenport for the Department of Genetics at Cold Spring Harbor is contained in Year Book No. 33 of the Carnegie Institution of Washington for 1934. It covers the usual wide range of investigations bearing on genetics in plants, animals and man. Only a few of these researches can be cited here. Demerec has surveyed the X-chromosome of *Drosophila* for minute deficiencies or cell-lethal mutations produced by X-rays. In 12 out of 13 cases the deficiency of a single locus caused cell death, which supports the view that nearly all the genes take a vital part in the functioning of every cell. In *D. virilis*, a gene producing intersexes has been found.

Blakeslee and Bergner find that, in *Datura discolor*, five of the twelve pairs of chromosomes have exchanged segments in comparison with *D. stramonium*, and these species when crossed give a ring of 10 chromosomes in the hybrid. Older seeds are shown by Cartledge to have a higher mutation rate than young seeds, and it was found that bad pollen could be used as an index of the mutation rate in aged seeds, which produced mutations at thirty times the rate of the controls.

Problems of leukæmia and immunisation in mice are investigated, and an account is given of Dr. Riddle's work on hormones, especially in pigeons. The antepituitary secretion has been most studied, both in pigeons and in cattle, some of the results receiving clinical application. It is shown that the gonad-stimulating hormone in rabbits also causes ovulation, but conclusive evidence is obtained that a separate pituitary principle stimulates the thyroid, also affecting the basal metabolism. The shaker mouse is found to show a defect in the *area striata* of the brain, and a circling mouse mutation is probably due to two recessive genes with variable expression. In the parasitic wasp, *Habrobracon juglandis*, Whiting has obtained sixty mutations. Some are sex-linked and form the basis for a theory of sex inheritance in this species with haploid males.

In human genetics there have been studies of growth in children, of the errors of physical anthropometry on the living subject, racial growth differences of Indians, Negroes and Dutch, and researches by Laughlin on immigration policy.

Educational Topics and Events

CAMBRIDGE.—The King has been pleased to approve the appointment of Dr. John Alfred Ryle to be regius professor of physic in the University in succession to Sir Walter Langdon Brown, who retires on September 30.

LIVERPOOL.—Dr. Hubert Horace Stones has been appointed Louis Cohen professor of dental surgery and director of dental education, from October 1 next, in succession to Prof. W. H. Gilmour, who retires at the end of the present session. Dr. Stones is an honorary dental surgeon to University College Hospital Dental School, London, and a research worker at the Hale Research Laboratory of the Royal Dental Hospital of London.

PROF. T. GRIFFITH TAYLOR, professor of geography in the University of Chicago, has been appointed professor of geography in the University of Toronto. This is the first independent chair of geography to be established in Canada. Dr. Taylor was associate professor of geography in the University of Sydney in 1920–28. He was senior geologist in Capt. Scott's last expedition to the south pole in 1910, and led other parties to the Antarctic in 1911–12.

EDUCATIONAL problems have in recent years engaged the attention of a multitude of investigators in the United States. In addition to the very numerous and comprehensive researches conducted by the staff of the Federal Office of Education, by State officials and by educational foundations, hundreds of systematic investigations have been carried out by candidates for the degree of doctor in education. A list of 797 theses submitted by such candidates and deposited with the Office of Education, where they are available for loan, has just been published by the Government Printing Office, Washington (pp. 69, price 10 cents). The titles are listed under a hundred subject headings arranged alphabetically, beginning with administration and ending with vocational guidance, with very full cross references under other headings. More than ten per cent of the theses are listed under the heading 'psychology'.

A DEPARTMENT of Business Administration was established at the London School of Economics in the University of London in 1930. Business men have from the outset played an active part in the work of the Department. At the end of the five-year experimental period, the Governors of the London School of Economics have decided, in view of the success which has attended the Department, to make it an integral and more permanent part of the work of the School. In that decision they are supported by the business men associated with the management of the venture. Several of the business firms which contributed towards the cost of the original experiment are generously continuing their financial support of the Department, and additional firms are also assisting. The active co-operation of business men in the actual conduct of the work is being continued in all its aspects, by the establishment of a Business Administrative Council of business men of widely diverse interests. A number of firms now favour the Department's University Scheme as a means of recruiting graduates. Some firms are in a position to offer appointments each year, others do so from time to time as vacancies occur. The post-graduate course of training, extending over one year of full-time study, remains the principal work of the Department. Students working for higher degrees, and wishing to undertake an investigation of a particular business problem as part of their work, may now combine attendance at the post-graduate course with their research. Particulars of the arrangements for the forthcoming session can be obtained from Prof. Arnold Plant, Department of Business Administration, London School of Economics, Houghton Street, Aldwych, London, W.C.2.

EDUCATIONAL broadcasting in the United States of America was discussed on May 15 at a conference called by the Broadcasting Division of the Federal Communications Commission. A statement made before the conference by the United States Commissioner of Education is reproduced in *School and Society* of June 15. It is remarkable for its insistence on the vital importance of safeguarding freedom of access to the microphone for exponents of all "the important ideas which struggle for acceptance in our complicated world order, so that our people can make intelligent choices in the determination of their destiny". The radio transmission systems in the United States being privately owned and operated, it is incumbent on the Federal Government to prevent their exploitation in the exclusive interests of any one body of doctrine and to ensure, on the contrary, the presentation of differing points of view in well-balanced programmes. With the progressive shortening of hours of labour in factories the field of influence of adult education by radio is rapidly expanding, and the Commissioner's announcement of his readiness to co-operate in a plan for the improvement of education by this means is timely. Much harm has been done by broadcasters imperfectly instructed in the technique of teaching by radio.

Science News a Century Ago

Death of Dr. John Brinkley, F.R.S.

ON September 14, 1835, Dr. John Brinkley, Bishop of Cloyne and Royal Astronomer of Ireland, died at his brother's house in Leeson Street, Dublin, at the age of seventy-two years. Born at Woodbridge, Suffolk, in 1763, he was enabled to enter Caius College, Cambridge, and in 1788 was senior wrangler and Smith's prizeman. While studying for his degree, he had assisted Maskelyne at Greenwich, and in 1790, largely through the influence of Maskelyne, he was chosen to succeed Henry Ussher as Andrews professor of astronomy in Trinity College, Dublin, and director of Dunsink Observatory, which had been erected under the superintendence of Ussher. A fine circle had been ordered for the observatory in 1785 from Ramsden, but this instrument was not completed until twenty-three years later, and Brinkley at first confined himself to mathematical work, contributing papers to the Royal Irish Academy and the Royal Society. On the erection of the 8-ft. circle at Dunsink he began researches on aberration and nutation, and made an attempt to determine the parallax of a fixed star. He also published his "Elements of Astronomy", which went through several editions, and his new theory of refraction, and computed the elements of the comets of 1819 and 1821. For this and other work he was made a vice-president of the Royal Society and president of the Royal Irish Academy, and in 1824 received the Copley Medal for his "Various Communications to

the Royal Society". Taking the degree of D.D. in 1806, he became prebendary of Kilgoghlin and rector of Derrybrush, in 1808 was made archdeacon of Clogher, and finally in 1826 bishop of Cloyne. His episcopal work from this time occupied much of his energy, and for the last ten years of his life he contributed little to science. He was buried in Trinity College Chapel, and a marble memorial to him was erected in Cloyne Cathedral. His best memorial, said Ball, was his admirable book on the "Elements of Plane Astronomy". He was succeeded in the Andrews chair by William Rowan Hamilton, whose genius he had long recognised.

Darwin in the Galapagos Archipelago

CHAP. xvii of Darwin's "Journal of Researches" contains his account of the visit of H.M.S. *Beagle* to the Galapagos Archipelago, the survey of which occupied from September 15 until October 20, 1835. "The archipelago," Darwin wrote, "consists of ten principal islands, of which five exceed the others in size. . . . They are all formed of volcanic rocks; a few fragments of granite curiously glazed and altered by the heat, can hardly be called an exception. Some of the craters surmounting the larger islands, are of immense size, and they rise to a height of between three and four thousand feet". Darwin landed on several of the islands of which, he said, the natural history is eminently curious and well deserving attention. "The archipelago is a little world within itself, or rather a satellite to America, whence it has derived a few stray colonists, and has received the general character of its indigenous productions. Considering the small size of these islands we feel the more astonished at the number of their aboriginal beings, and at their confined range. Seeing every height crowned with its crater, and the boundaries of most of the lava-streams still distinct, we are led to believe that within a period, geologically recent, the unbroken ocean was here spread out. Hence both in space and time we seem to be brought somewhat near to that great fact—that mystery of mysteries—the first appearance of new beings on this earth".

Green's Night in a Balloon

CHARLES GREEN (1785–1870), the first aeronaut to make an ascent with carburetted hydrogen gas, spent a night in the air on September 17, 1835. Writing to *The Times* on September 20, 1835, on his late aerial voyage from the Royal Gardens, Vauxhall, he said he ascended with Mr. Butler at quarter to six on Thursday evening, September 17, and at about quarter past six descended at Walthamstow. He then determined to stay in the air all night so, leaving Mr. Butler behind, he reascended, passed over Bishops Stortford, Royston and Huntingdon and at quarter to six on Friday morning landed in the parish of Wimbotsham, near Downham in Norfolk. He partook of an excellent breakfast at the residence of Mr. J. Pike. Then he again ascended and descended at 10.30 a.m. near Lynn, Norfolk. "I received numerous congratulations," he said, "though many persons I believe doubted the statement of my having been in the air during the past night. . . . I remained in the air altogether about 13 hours and from the zigzag direction of my course must have travelled about 130 miles. From the very trifling loss of power the balloon sustained during the whole of this time, I judge I might have remained up at least five days and nights."

Societies and Academies

PARIS

Academy of Sciences, July 22 (*C.R.*, **201**, 245–308). LOUIS BLARINGHEM: A new case of unilateral heredity observed on hybrids of sages (*Salvia nemorosa* × *S. Sclarea*). STANISLAS GOLAB: The relation between the ideas of measurements of angles and areas in Finsler spaces. ANDRÉ FOUILLADE: Unicity with a nearly constant factor, in an undecomposable ensemble, of a function of the ensemble invariant with respect to the transformation associated with a positive, linear functional transformation maintaining unity. JEAN BRAÏTZEFF: A particular case of the distribution of the singular points of a function defined by a Dirichlet series. MIÉCISLAS BIERNACKI: Some majorants of the theory of univalent functions. PAUL NOAILLON: Sudden expansion in a gas. MIROSLAV NÉNADOVITCH and MAURICE DENIS: Contribution to the experimental study of the stability of certain biplane cells at large incidences. P. CHEVENARD and X. WACHÉ: The accelerating effect of a sinusoidal mechanical tension on the changes in a hypertempered iron-nickel-chromium-carbon austenite. The accelerating effect of the sinusoidal pressure on the precipitation of the carbides is very marked. This results in a certain increase in the mechanical resistance when hot; but in some cases leads to fragility, giving rise to breakage without sensible deformation. RAYMOND TREMBLOT: A contrast star photometer. A modification of the Fabry and Buisson photometer without diffusing screens allowing a better utilisation of the light available when the measurements are carried out on point sources of light of very small luminosity. An accuracy of 0·01–0·02 magnitude is possible. ANDRÉ LÉAUTÉ: The capillary ascent of tars and bitumens. Application of the method previously described to the study of the causes of the changes in a road surface, originally satisfactory but later slippery. MME. LINA GUASTALLA: The oxido-reduction process at the level of a (kaolin) partition interposed in a copper solution, in the course of electrolysis. The factors determining the velocity of its appearance. MARCEL CAU and FÉLIX ESCLANGON: The coherence of light radiations and the possibility of using interference apparatus as monochromatic light sources. WITOLD BRONIEWSKI and W. LEWANDOWSKI: The influence of sulphur on the properties of copper. Amounts of sulphur varying from 0·0 to 0·7 per cent were added to copper, and measurements made of the changes in electrical conductivity, temperature coefficient of the electrical conductivity, thermo-electric power (against lead), breaking load, elastic limit, elongation before breaking and Brinell hardness. The results are given graphically. ROGER PERROT: The action of nitrosyl chloride on some silver salts. M. TIFFENEAU, P. WEILL, J. GUTMANN and B. TCHOUBAR: Molecular transpositions in the cyclane series. Lengthening and shortening of the rings. CHARLES DUFRAISSE and ANDRÉ ETIENNE: The dissociable organic oxides. The anthracene structure possesses reversible oxidisability: a dissociable oxide of mesodiphenylanthracene. From the study of the rubenes, the authors have deduced a structure for substances capable of reversible photoxidation, and mesodiphenylanthracene possesses such a structure. This substance has been found to absorb free oxygen, forming a crystallised photo-oxide: it dissociates at

200° C. into pure oxygen and the free hydrocarbon. ALBERT F. DE LAPPARENT: The Trias band of Barjols (Provence). JACQUES FROMAGET: The existence of the lower Trias with ocean facies to the south of Luang-Prabang (Laos) and on the palæogeography of south-eastern Asia at this period. CHARLES PÉREZ: Stages in the disappearance of the roots of *Peltogaster* after the fall of the visceral sac. PIERRE GRASSÉ and PAUL BONNEVILLE: Non-swarming imagos or achrestogonimes of the Protermitids. MARIUS BACCINO: The thermal adaptation of the nests of mammals during the growth of the young. The temperature of the nest in the case of rabbits falls as the age of the young increases. For each age there is a temperature of maximum growth. ALBERT and PAUL CHAUCHARD and MME. BERTHE CHAUCHARD: The action of nicotine on the preganglion and postganglion sympathetic nerve fibres. FRIEDRICH L. HAHN: The determination of very small quantities of ethyl bromide in biological media. ANDRÉ KLING, EMILE GELIN and JULES DEMESSE: The possible substitution, for the analysis of various natural plant products or their derivatives, of the determination of total carbon for that of the dry extract. The carbon dioxide obtained on oxidation with chromic and sulphuric acids gives a measure of the dry extract with sufficient approximation and offers a considerable saving in time. EDGAR LEDERER: Echinenone and pentaxanthine: two new carotinoids found in *Echinus esculentus*. A. BESREDKA, J. MAGAT and P. BESNARD: The vaccination of rabbits against cutaneous epithelioma. EMILE ROUBAUD and MARC TREILLARD: A coccobacillus pathogenic for tsetse flies.

GENEVA

Society of Physics and Natural History, July 4. E. BRINER, F. CHODAT and H. PAILLARD: The presence of ozone in the air, and its action on the growth of plants. B. SUSZ, E. PERROTTET and E. BRINER: Raman spectra and reactivity: eugenol, isoeugenol, vanillin and methyl derivatives, safrol, isosafrol, heliothropin, anethol and estragol. M. A. PUTNES: Stokes's theorem for heterogeneous ellipsoids in permanent rotation. R. WAVRE: Figures of equilibrium. K. H. MEYER and G. W. PANKOW: The chloride of polyphosphonitrile. P. WENGER, Ch. CIMERMAN and MLLE. C. RZYMOWSKA. The volumetric micro-estimation of potassium in blood serum. L. A. DESHUSSES and J. CORBAZ: (1) The fractionation of oily constituents by distillation. (2) The separation of oily constituents by extraction with ether. E. CHERBULIEZ and A. MIRIMANOFF: The differential estimation of the polypeptides and aminoacids of the serum by the use of ninhydrin. HELD and MLLE. PONSE: The thyreostimulating activity of the blood of thyroidectomised or normal guinea-pigs. F. WYSS-CHODAT. (1) Notes on transmissible microbial lysis. (2) The reducing power of milk. Reductase and coreductase. A. MIRIMANOFF: (1) The estimation of the aminoacids of the blood serum by tyrosinase. (2) Remarks on the growth factors of the must of grapes. E. BRINER, S. FRIED and B. SUSZ: The Raman spectra of solutions of pyrogallol, gallic acid and tannin. E. PITTARD: Intentionally broken teeth of the ox and horse of the Mousterian period. T. POSTERNAK: (1) The phosphorus of starch. (2) A new tetroxyadipic acid.

LENINGRAD

Academy of Sciences (*C.R.*, 2, No. 7, 1935). RENÉ CALAPSO: Configuration (T) of Finikoff and the projective elements attached to it. N. V. ADAMOV: Some conditions of stability. B. V. NUMEROV: Problem of the determination of systematic errors of star positions. D. N. CHRAMOV: Determination of anomalous values of the vertical gradient of gravity from the anomalies of gravity. E. M. BRUMBERG: A new method of producing monochromatic light. V. FREDERICKS, G. MICHAJLOV and D. BENESZEVICH: Dielectric losses in anisotropic fluids. B. I. DAVYDOV: Diffusion equation with reference to molecular velocity. A. G. SAMARCEV: Cathodic passivity of silver in solutions of silver nitrate. A. A. GRÜNBERG and L. M. WOLSTEIN: Mechanism of action of glycocol on potassium tetrachloroplatinate. I. N. EFIMOV: Modifications of facial conditions along the strike of the roofing of coal measures in the Donetz basin. A. A. PROKOFJEVA-BELGOVSKAJA: The structure of the chromocentre. S. G. LEVIT: Dominance in man.

SYDNEY

Royal Society of New South Wales, July 3. ADOLPH BOLLIGER: Volumetric microdetermination of magnesium with methylene blue following its precipitation as magnesium picrolonate. Magnesium, as well as calcium, forms a sparingly soluble picrolonate which, however, in contrast with calcium picrolonate, is not precipitated from dilute solutions at room temperature. However, magnesium salts were found to be precipitated quantitatively as magnesium picrolonate by heating and partially evaporating the solution in which they are contained. The analytical principle applied is as follows: a known excessive amount of lithium picrolonate is added to the aqueous solution containing the magnesium, precipitation is brought on by heating and evaporation, and the excess of picrolonate added is determined by titration with methylene blue. The limitations of the method are discussed. G. F. K. NAYLOR: Note on the geology of the Goulburn district, with special reference to Palæozoic stratigraphy. The first record of Lower Silurian strata in this State. These rocks were identified by their content of graptolites, a group of organisms the remains of which have also proved invaluable in determining the extent of the Upper Ordovician and Upper Silurian strata in the same district. The author shows that, on palæontological and structural evidence, the Palæozoic strata near Goulburn form a broad synclinal structure, the core of which is occupied by the Upper Devonian mass of the Cookbundoon Mountain, and the hill on which the Goulburn War Memorial is situated.

VIENNA

Academy of Sciences, July 4. ERNST SPÄTH and FRIEDRICH BECKE: Cactus alkaloids (15). Separation of anhalonium bases. GUIDO MACHEK: Action of aromatic sulpho- and oxysulpho-acids on α- and β-amino acids. ERNST FÖYN, ELISABETH KARA-MICHAILOVA and ELISABETH RONA: Artificial transformation of thorium by neutrons (1). GUSTAV ORTNER and RICHARD ZENTNER: Measurement of the natural breadths of X-ray lines. The possibilities of using a single-crystal spectrometer for measuring these breadths photographically were investigated.

ELVIRA STEPPAN: Problem of the disintegration of aluminium, treated by the photographic method. JOSEF SCHINTLMEISTER: The question of the existence of unknown natural α-rays. These rays, of range $R_{15} = 2{\cdot}2$ cm., occur always in conjunction with samarium and exhibit marked chemical affinity with this element. The carrier of the activity observed is most probably thulium or, at any rate, element No. 61. HEINRICH MACHE and GEORG MARKSTEIN: Output of emanation to water flowing over radium-containing rocks. The view has been expressed that, owing to the slight capacity of rocks for occluding indifferent gases, the quantity of emanation passing into spring water per unit of time and per unit of rock-surface must be independent of the concentration of the emanation present in the water. Experimental results now obtained agree with this view. RUDOLF KANITSCHEIDER: Terrestrial magnetic observations of the Austrian Polar Expedition to Jan Mayen, 1932–33. The results obtained for 1933·0 are: declination, − 22° 40′; horizontal intensity, 11,700γ; vertical intensity, 50,400 γ. H. L. WERNECK: Phenology of Upper Austria, 1926–30. OTTO FÜRTH and HEINZ HERRMANN: Colour reactions of tartaric, citric and aconitic acids. When heated with pyridine and acetic anhydride, citric acid gives a carmine, aconitic acid a violet-red, and tartaric acid an emerald-green coloration. J. P. REIMER: Nebulæ in the region of *o*-Persei. HANS KRUMPHOLZ: Course of the brightness of Nova (1934) Herculis to the beginning of April 1935. FRANZ RINAGL: Flow limits and bending. ARMIN DADIEU and WOLF ENGLER: Raman spectra of C_2H_5SeH and C_2H_5SeD. The frequencies for the SeH − (2303 cm.$^{-1}$) and SeD − (1665 cm.$^{-1}$) vibrations agree well with those previously found for SeH_2 (2313 cm.$^{-1}$) and SeD_2 (1665 cm.$^{-1}$). ARMIN DADIEU and OTTO KERMAUNER: Structure of half-heavy acetylene. Comparison of the Raman spectra of C_2H_2, C_2D_2, and a product obtained from CH : CNa and D_2O indicates that this product contains about 50 per cent of C_2HD, with 25 per cent each of C_2H_2 and C_2D_2. The product of the reaction of C_2Na_2 with a mixture of D_2O and H_2O in equal proportions gives a spectrum identically the same. ALFONS KLEMENC, R. WECHSBERG and G. WAGNER: Preparation of carbon suboxide. The separation of carbon suboxide from its mixture with carbon dioxide and keten, obtained from diacetyltartaric anhydride, is described. MORITZ KOHN: Action of oxalates on blue iron-cyanogen compounds. OTTO DISCHENDORFER and AUGUST VERDINO: 2:6-Dibenzoylhydroquinone. K. W. F. KOHLRAUSCH and GR. PRINZ YPSILANTI: Raman effect (45). Raman spectrum of organic substances (polysubstituted benzenes, 7). The substances examined were of the type, $X.C_6H_4.OCH_3$, where X = NH_2, OH, CH_3, F, Cl, Br, I, or CN. A. PONGRATZ and R. SEKA: Raman spectra of benzenepolycarboxylic esters. Methyl and ethyl iso- and tere-phthalates, and trimethyl benzene-1:2:3-tricarboxylate were examined. The C–C ring linkings behave similarly to those in open-chain unsaturated compounds. K. W. F. KOHLRAUSCH and W. STOCKMAIR: Raman spectra of nucleus-substituted ethyl benzoate. The substituents were NH_2, OH, Cl, Br, NO_2. EUGEN GUTH: Theory of the scattering of charged particles at atomic nuclei (with a special application to the scattering of protons at protons). KARL SCHWARZ: Transport number and valency of silver in silver amalgam. VICTOR F. HESS: Daily course of cosmic ultra-radiation. Wagner's criticisms are discussed.

Forthcoming Events

IRON AND STEEL INSTITUTE, September 16–18. Autumn meeting to be held in Manchester.

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX, September 20–23.—Annual conference to be held in St. John's College, Cambridge.

Sir Richard Gregory: "Interpretation of Science" (Presidential Address).

No. 3438 SATURDAY, SEPTEMBER 21, 1935 Vol. 136

The Forestry Commission*

THE fifteenth annual report of the Forestry Commission presents a record of the work carried out by the Commissioner since its establishment in 1919. The fifth and the tenth annual reports gave similar general reviews of the work done in the first and the second quinquennium respectively.

The wide and expanding scope of the work which is being carried out by this young and energetic Government Department is shown at a glance by the full 'contents' of the report before us. In spite of its fifteen years of existence, the Forestry Commission is still merely in the first phase of its existence; the Commission, like the forest, cannot be regarded as full fledged and in full working order until a complete forest rotation has run its course, and, as is well known, a forest takes many decades to reach maturity. The Transfer of Woods Act, 1923, however, placed fifty-six thousand acres of existing forest under the care of the Forestry Commissioners, and this brings under their administration the whole range of forestry practice. Nevertheless, the chief function of the Commission is meantime to create and re-establish forests adequate to supply at least part of the needs of Great Britain in timber of economic value.

At September 30, 1934, the Commissioners had under their charge approximately 909,000 acres of land, which gives an indication of the progress made since 1919. A further idea of the progress being made in afforestation by the Commissioners is afforded by the number of manual workers employed in their forests. The summer minimum in 1920 was 210; and the winter maximum in 1920–21 was 935. In 1934, the summer minimum had increased to 3,015, and the winter maximum of 1934–35 was 4,020. The intermediate figures of employment show a steady increase during the intermediate years, and as time goes on the numbers are bound to increase not only as the area under forest expands, but also as the plantations approach the thinning stage. These operations will involve cutting, haulage, preparation, and road, rail and to some extent sea transport to the mines and other timber consuming centres. A drop of a thousand or two in the figures of unemployment is hailed with delight as a sign of economic progress and recovery. This new national industry, set upon its feet by the establishment of the Forestry Commission, is undoubtedly pulling its weight.

The funds at the disposal of the Commissioners are being deposited in a safe bank. If we look at the question from the point of view that it is not the forester but Nature which produces the timber, we get a clearer idea of the economic basis of forestry. The forester by his labour and a certain amount of capital outlay in material produces conditions which enable Nature to become his ally in the direction he desires. Once he has placed the right tree in the right environment, natural growth factors such as sunlight and temperature, with a suitable amount of air and soil moisture, enable the living machine to get to work and from the carbon dioxide of the air and a small amount of mineral food materials from the soil, timber, which consists mainly of carbon, is produced. The raw material is cheap and abundant. The carbon from the air costs nothing and the small quantity of minerals from the otherwise idle soil is being put to a useful purpose, and as time goes on the productive capacity of the soil is improved, under suitable sylvicultural management. Surely then, something for nothing, with

* Forestry Commission. Fifteenth Annual Report of the Forestry Commissioners for the year ending September 30th, 1934. (London: H.M. Stationery Office, 1935.) 2*s*. net.

raw material inexhaustible, if properly used, is an attractive proposition. The forest capital is increasing in direct ratio to the rate of growth of the trees. The forester organises the industry in which Nature supplies the driving power and the raw material. The trees are his 'workmen', which if properly treated are busy night and day with no 'off' time or unemployment. There are therefore, surely, a few concerns in which money, especially national funds, can be applied with more safety or greater mutual benefit to all.

A perusal of the Forestry Commissioners' report shows that everything possible is being done in regard to land acquisition and planting, education, research, and the development of forest technique. Research and experiment in regard to the production of timber under varying conditions, the establishment of new plantations, the treatment, protection and utilisation of established plantations, have already led to improved and more efficient methods of practice. Sound methods of practice depend upon as complete a knowledge as possible of the biology of our trees and of the forest as a whole. One of the weak points in British forestry until now has been our almost complete neglect of the study of the relationship between our trees and soil. This has been due mainly to lack of men and facilities, but it will be remedied in the future, as the Commissioners have made a grant to the Macaulay Institute for Soil Research at Craigiebucklar near Aberdeen for the investigation of forest soils, including questions relating to the fertility of forest tree nurseries. Such investigation, in conjunction with studies in forest biology, is the safest method which is likely to lead to improvement in the productive capacity of our existing forest soils and to bring many extensive areas at present considered doubtful or unsuitable for tree growth into a fit state for afforestation.

Nor is the æsthetic aspect of forestry being neglected. The provision of future national forest parks is being kept in mind. The forests are still too young to permit of general access by the public, but in due course suitable areas will be opened up for health and recreational purposes. The Commissioners are co-operating with the Director and staff of the Royal Botanic Gardens at Kew in the formation of a new arboretum at Bedgebury near Goudhurst in Kent, away from the smoke and fumes of London. The arboretum is being laid out to show fine specimen trees singly and in groups. At Benmore in Argyllshire, an estate comprising 10,200 acres was gifted to t Forestry Commission in 1925 by Mr. Harry Geo Younger, and three years later he generou augmented his gift of land by creating a tru known as the Younger Benmore Trust, the inco from which is used for the maintenance of t gardens and grounds, which are now open to t public. The gardens, by arrangement with H.M Office of Works, have been placed under th control of the Regius Keeper of the Royal Botani Garden, Edinburgh. The rest of the estate administered by the Forestry Commissioners.

Forest worker's holdings, which were not part of the original programme of the Commission were started in 1924 as a scheme of land settlement, but since 1931, the creation of new holdings has been restricted to such as are essential to the proper working of the forest. The number of forest workers resident on the holdings is 1,176, and including their families there is a total residence on the holdings of 4,978. Figures compiled from careful records show that, as a whole, the holders, most of whom started with no capital, now own live stock to the value of £43,173.

In co-operation with the Ministry of Labour, instructional centres and camps have been established, about twenty-eight in all, near land belonging to the Commissioners. Each centre accommodates about two hundred men, who are drawn from areas of heavy and prolonged unemployment, and are given a three months' training course to develop physical fitness. The type of manual work provided for the trainees consists mainly in clearing sites for forest roads, quarrying stone and laying road foundations, the building of bridges and culverts, land drainage, scrub clearing and grubbing roots—constructive work which will be of permanent value.

A series of four sketch maps illustrating the progress of the acquisition of forest units at the end of each five years from 1919 until 1934, shows an increase from eighteen units in 1919, to one hundred and eighty-six units in 1934.

Under the exceptionally difficult conditions, especially in rural areas, which have existed since the War, it is not surprising to learn that afforestation by private owners has not come up to the expectations of the Acland Committee Report. The Commissioners have done their best to come as near as possible, in the circumstances, to the provisions for the acquisition of land laid down in that report, but much leeway in both State and private effort still remains to be made up, and

irely now is the time when the State can, with resent and future advantage, speed up the evelopment of forests and forestry.

In presenting this review of their first fifteen ears' work, the Forestry Commissioners are able o show a creditable record of achievement. The foundation for the future development of State orestry has been well laid and, as time goes on, we shall begin to reap the increasing benefits, industrial, economic and social which cannot fail to follow a wise forest policy. This report is of outstanding national importance, and the reader who is interested in the development of forest policy in Great Britain will, we feel sure, conclude that the interests of the country in this respect are in safe keeping.

Inductance, Capacitance and Frequency Measurement

The Measurement of Inductance, Capacitance and Frequency

By Albert Campbell and Dr. Ernest C. Childs. Pp. xxiv+488. (London: Macmillan and Co., Ltd., 1935.) 30*s*. net.

WHEN we consider that all matter is composed of electric ions which are in constant oscillation, it is evident that the study and measurement of electrical oscillations must always remain a leading feature of physical investigations, and the measurement of inductance, capacitance and frequency over an enormously large range must form a major part of laboratory testing. But this wide range of frequency, from a few cycles per second to the hundreds of acoustic measurements, the millions of wireless signalling, the billions of thermal and luminous radiation, and the trillions of X-rays, calls for constant development of such methods as different sections of the frequency range are utilised, so that the number of methods of measurement is already legion and must become even larger in the future.

However familiar the laboratory worker may be with certain methods, he is unlikely to select the method which is most suitable for any particular purpose, without a comprehensive survey of all the various methods and devices now available; and a single volume in which they are described and critically compared has long been needed. Mr. Campbell's inventiveness and long experience in this sphere renders him specially qualified to write such a volume, and in conjunction with Dr. Childs he has produced a book which should be at hand in every test room, and is likely to remain the standard work on the subject for many years to come.

Those who are familiar with Mr. Campbell's articles in the "Dictionary of Applied Physics" will recognise the simple concise manner in which the various methods and instruments are described; all essential theory being included without redundant detail or complexity. These articles form the nucleus of the present volume; but the sections dealing with vibration galvanometers and inductance and capacitance measurements have been greatly expanded, and the value of the book has been greatly enhanced by the addition of a long chapter on frequency measurement, and, especially, by four chapters on alternating current potentiometers. The latter addition is especially welcome, as, in spite of the great convenience, universality and range of alternating current potentiometers, they have hitherto been little used, and it is to be hoped that this account of them and indication of their many applications will conduce to their wider appreciation and use.

A brief opening chapter on alternating current theory is followed by one on sources of current which describes various forms of alternators, interrupters, microphone and tuning fork hummers, arc and valve oscillators, and frequency stabilisers. Chapter iii, on measuring and detecting instruments, includes electrodynamometers, alternating current galvanometers, thermal instruments and telephones, amplifiers, rectifiers and valve-voltmeters; while Chapter iv, on vibration galvanometers, describes practically all the types which have been devised, with their theory and application. Resistances for use in inductance measurements are dealt with in Chapter v, which includes all the best-known types of anti-inductive resistances, including tubular forms, but reference might have been made to the extremely valuable tubular resistance of A. E. Moore which is the only perfectly non-inductive one.

Inductance measurements occupy Chapters vi–xiv, commencing with the calculation of inductances both by rigid methods and the most convenient approximate formulæ, and passing on to the construction of mutual inductances, including of course the valuable Campbell types of absolute standards and variable inductors; transformers; construction of fixed and variable self-inductors; electrical networks and bridges; measurement of mutual inductance; testing of transformers; measurement of self-inductance and

effective resistance; and inductance of measuring instruments.

Condensers and capacitance measurement are considered in Chapters xv–xviii, dealing respectively with theory; dielective constant and power loss; construction of condensers; and methods of measurement. This portion of the work contains much useful information concerning the properties of dielectrics.

Chapter xix, on the measurement of frequency, covers a very wide field from counters and synchronous motors, and standard frequency control to stroboscopes, resonance and deflectional frequency meters, bridge methods and wave meters.

The remaining four chapters, xx–xxiii, on alternating current potentiometers, deal respectively with their general principles and history; theory of phase splitters; description of various alternating current potentiometers; and uses of alternating current potentiometers. As above stated, these form one of the most novel and important features of the book.

The whole volume is attractively got up and clearly illustrated, and a short bibliography of the most important papers on each subject is included at the end of each section, as well as an appendix of books of reference. Copious references to special papers are provided in the text. C. V. D.

A Landmark in the Study of Optical Activity

Optical Rotatory Power

By Prof. T. Martin Lowry. (Text Books of Physical Chemistry.) Pp. xiii+483. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 30*s*. net.

IN view of Prof. T. M. Lowry's remarkable industry as an investigator, it is a matter for further admiration that he should be able to produce, as a sort of by-product, this extensive work on optical activity. Nothing of an equally original character has hitherto appeared in book form in English; and its arrival is very welcome on that account, as also because it is an attempt to give a conspectus of the whole field, including, happily, the historical development of the subject.

The first of the four parts into which the book is divided is general in character, and deals briefly with the phenomena leading up to the discovery of the polarisation of light by reflection from glass; the discovery of the rotation of the plane of polarisation in quartz; with Fresnel's views; with the work of Pasteur; and with rotatory dispersion, circular dichroism and magnetic rotatory power.

Part ii, covering nearly one hundred pages, is devoted to a description of the apparatus used in various kinds of polarimetric work, and will doubtless be found very useful in giving a clear idea of the principles underlying the operation of many instruments presently in use; but inexperienced readers may occasionally be a little misled by the fact that the two Nicol prisms, which form part of much of such apparatus, are usually, or always, shown in the parallel position, whereas in fact their action depends upon their principal planes being almost at right angles.

In Part iii are discussed a number of important topics, such as muta-rotation, optical superposition, anomalous dispersion, induced dissymmetry and circular dichroism; whilst Part iv deals with theoretical considerations, too various to specify, but concerned largely with electrons and circular dichroism.

In spite of the wide range of the work, it may, nevertheless, scarcely be described as a textbook. It is, rather, a comprehensive monograph; since it deals so largely with the views and work of the author himself, or with such views and work as he happens to approve of. This is not said in disparagement: rather the contrary, since a description of an author's own views is likely to be more stimulating than would be his description of the views of others. But it is surprising that Alexander McKenzie's work, notably in regard to the Walden inversion, to asymmetric synthesis and to asymmetric induction should receive no mention at all.

In the first edition of a book which contains so much matter, it would scarcely be possible altogether to avoid mistakes. There are, here, at least two which might easily be very misleading. On p. 330 is given a diagram, taken from one of Winther's papers, which professes to represent the specific rotation of nicotine in different solvents. In fact, however, it represents that of ethyl tartrate, the mistake being due to two blocks in the original publication having been interchanged. The correct diagram is given in *Z. phys. Chem.*, 60, 652; 1907. Fig. 48 also, on p. 154, which purports to represent Cotton's results, although given originally by Cotton himself (*Ann. Chim. phys.*, [7], 8, 408; 1896), is also incorrect. As Cotton pointed out in a later paper (*J. Phys.*, [3], 7, 84; 1898) the curve of ellipticities shown here ought to be inverted.

Generally speaking, however, those parts of the book dealing with facts, either regarding apparatus or experimental results, will be found clear and useful. The theoretical parts, at least to the present reviewer, appear much less convincing and satisfactory. They are, certainly, altogether in the modern style, but are really a kind of make-believe, of superficial plausibility—little more than casuistry. Thus, although it is some sixty-three years since Arndtsen first suggested that what is arbitrarily termed 'anomalous' rotation-dispersion is due to the presence of isomers, and this is the popular view to-day, no progress whatever has been made in identifying or isolating these highly elusive isomers, except by showing that a large number of other compounds also exhibit the same phenomenon. The idea, however, by constant iteration, appears to be regarded, popularly, as proved, although the argument amounts merely to this: "Why does this compound—tartaric acid for example—exhibit anomalous rotation-dispersion?" "Because it contains two isomers of opposite and different dispersion." "How do you know that it contains two isomers of opposite and different dispersion?" "Because it exhibits anomalous rotation-dispersion." It is the same kind of argument that Lavoisier exposed very devastatingly: "Why does a substance burn?" "Because it contains phlogiston." "How do you know it contains phlogiston?" "Because it burns."

Similar criticism could easily be directed against most of the theoretical parts of the book. Optical superposition is referred to in various places, but none of the work described can give a definitive solution of the problem, whilst the only work on record which, from the theoretical point of view, is sound, is not mentioned at all.

In regard to solvent influence on rotation, a numerical parallelism can be instituted in several cases between rotation and dipole moment. The large number of exceptions are then, quite arbitrarily, attributed to some other cause, such as association, without any kind of proof that association—if it occurs at all, which is doubtful—does affect rotation. The causes are mere *Dei ex Machina*.

Two other examples will show how facile is modern argumentation. If, in the substance $\begin{matrix}CH_3\\C_2H_5\end{matrix}\!\!>\!CXY$, the CH_3 group is replaced by a C_2H_5 group, the resulting product will be inactive, but, according to Prof. Lowry (p. 303), if the CH_3 is replaced by C_3H_7 "It is generally admitted that the sign of the rotation will be reversed", and an argument is actually founded on this exceedingly slender basis. There does not seem to be a particle more than a 1 : 1 chance of this general admission being true (the result would probably vary with the nature of the groups XY, the solvent, colour of light, concentration and temperature); and arguments, in any event, ought to be founded, not on general admissions, but on experimental facts, which, here, are lacking. Again on p. 364, Prof. Lowry approves Boys's attempts to calculate certain rotations, "in spite of the impossible character of the assumptions made in reference to the more complex radicals". It is to be hoped that conclusions based upon impossible assumptions will not become too common.

In spite of such criticisms, however, the book is a notable addition to the literature of optical activity: a production of which the author and the publishers may well be proud.

T. S. PATTERSON.

Experimental Linguistics

L'Analisi elettrocustica del linguaggio

Per Agostino Gemelli e Giuseppina Pastori. (Pubblicazioni della Università Cattolica del Sacro Cuore, Serie 6: Scienze biologiche, Vol. 7.) 1: Testo. Pp. xxviii+250. 2: Atlante della tavole. Pp. iii+88 plates. (Milano: Società Editrice "Vita e Pensiero", 1934.) 2 vols., 75 lire.

FOR the purpose of studying spoken language from the linguistic point of view, the authors obtained registrations on strips of sensitised paper by means of a microphone connected to a wire-loop oscillograph (Duddell). One of the problems handled is the nature of the vowels. A curve of *ah*, for example, is divided by the authors into 75 vibratory bits of similar, but not identical, character occurring in immediate succession. To obtain a numerical expression for the curve in a vibratory bit two methods are used. In one of them the form of the wave—the vibration profile—is expressed as the sum of a series of sinusoids with frequencies in the relations 1, 2, 3, . . . whereby the number 1 corresponds to the number of times with which the entire length of the wave could be repeated in 1 sec. (Fourier polynomial, harmonic series). With the other method (Vercelli) the wave form is expressed as the sum of a set of sinusoids in the series 1, .., .., ... in which the number 1 has the same meaning as in the harmonic series and the other numbers may stand in any relations whatever to the first one.

The results with both methods agree in having

very small values for the first member ; in all other respects the results disagree completely. The harmonic analysis showed strong amplitudes occurring in groups and small amplitudes everywhere else. The Vercelli analysis showed a few strong amplitudes that were not grouped ; these belonged to frequencies not harmonic to the first member. The authors do not attempt to explain the complete discrepancy or to interpret either set of results. The fact that every vibration profile consists of a wave movement that begins strong and fades rapidly to zero is quite overlooked. A prime characteristic of such a wave is its factor of decrement. Neither of the two series provides for an expression of the decrement. It shows itself by modifying the values for the amplitudes, by producing amplitudes for all members and by adding a meaningless constant. Vibrations with decrements may be aroused by suddenly releasing a spring, by uncorking a bottle, by snapping the thumb out of the mouth or by suddenly releasing a pressure of the air at the glottis with the mouth open. The curve of the vibration from the spring is a slowly fading one with smooth waves. That from the bottle is a rapidly fading one with smooth waves. That from the mouth in the last two cases is exactly like a curve of a vibratory bit in a vowel ; the sound is, in fact, a real vowel consisting of only one bit.

The results of Fourier and Vercelli analyses of various vowels are given. The authors reach the conclusion that the specific nature of a vowel vibration is not the result of the presence of a specific frequency or frequencies (Willis-Helmholtz-Hermann theory of formants) or of specific relations among the frequencies (Lloyd), but of a special complex of elements to which they apply the term 'specific character'. The specific profile is the expression of the specific character. Just what elements go to produce the specific characters remain unstated. This view is identical with that expressed in the profile theory, according to which vibratory bits are perceived as unanalysed profiles (NATURE, 130, 275 ; 1932).

By an extension of the term, it becomes possible to speak of the profile of a whole vowel, of a word, of a phrase, etc. Just as a vibratory bit is perceived as a profile without analysis, so a whole vowel is perceived as a profile without analysis into vibratory bits, a word as a profile without analysis into speech sounds, a phrase as a profile without analysis into words, etc. Interesting in this connexion is the fact that when speech vibrations are amplified sufficiently to be perceived by the sense of touch (Gault's teletactor) the tip of the finger recognises the various vowels, consonants, words and phrases by their vibration profiles.

The physical vibrations are expressions of what the speaker 'intended to say'. The ultimate unit of inner speech—that is, of language—is termed a 'phoneme'. This is defined by the authors as "any sound or noise used in language that cannot be divided into other elements of language but only into vibratory phenomena". The phonemes include vowels, semi-vowels and consonants. It is to be clearly understood that these are inner (or psychic) units, and not physical ones. The word *luna*, for example, is assumed to be composed of four speech sound phonemes indicated by the letters *l*, *u*, *n*, *a*. The authors divide the registration of this word into four portions and consider each portion as the expression of one phoneme. According to the authors, the word consists both psychically and physically of a succession of four portions. The registration, however, shows that the characteristics of the wave forms present during the portion assigned to *l* are present also in the waves of the first part of the portion assigned to *u*, and, conversely, characteristics of the waves in the portion assigned to *u* can be traced in the waves of the last part of the portion assigned to *l*. This indicates that the phonemes *l* and *u* were overlapped before they were expressed in physical speech. The phenomenon of overlapping occurs everywhere in the registrations. The word *luna* is to be considered as the sum of the four speech sound phonemes occurring not in succession but with overlapping. The registration of the word must be taken as a whole ; it cannot be divided into a succession of sounds.

Fifty years ago, Rousselot sought to overcome the impossibility of analysing speech by listening to it. To register it on a phonograph would have been of no use, because all he could have done with his registrations would have been to listen to them again. The oscillograph and the sound film had not been invented. The method that he devised consisted in placing a cuplike receiver over the mouth and the end of a tube in a nostril and conducting the changes in the breath issuing from the mouth and nose to membranes the movements of which were registered on a moving surface. His registrations were of the mass movements of air that constitute macrophonic speech (see NATURE, 132, 138 ; 1933). Macrophonic speech produces microphonic speech by arousing vibrations in the vocal cavities. The authors of this work have contributed to the foundation of linguistics as an exact science by analyses of microphonic speech. They make use of comparisons with macrophonic registrations. With these and some other methods linguistics begins to become a science based on numbers.

E. W. SCRIPTURE.

Weather Parallels and Paradoxes

(1) Through the Weather House: The Wind, the Rain, and Six Hundred Miles above. By R. A. Watson Watt. Pp. xi+192+8 plates. (London: Peter Davies, Ltd., 1935.) 3s. 6d. net.

(2) Weather Proverbs and Paradoxes. By Dr. W. J. Humphreys. Second edition. Pp. xii+126+16 plates. (Baltimore, Md.: The Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1934.) 9s.

(1) EARLY in 1934, Mr. Watson Watt gave a series of broadcast talks on weather which attracted considerable interest from the novelty of the treatment and the vividness of the imagery. These talks have now been published in a very readable book, illustrated by some good cloud pictures. The "Weather House" as pictured in the frontispiece is a super-sky-scraper of ultra-modern design, with a hundred stories each six miles high, fitted with all modern conveniences in the form of electric lighting, heating and decoration, and all supplied by 'wireless'.

The matter is the familiar matter of any popular textbook on meteorology, with a few additions from the author's special sphere of research, but the exposition is very clear and is certainly helped by the analogies with domestic appliances, though to the meteorologist these become a little tedious at times. Water in various forms naturally plays a large part—"Damp in the Weather House", "Cloud-Weaving", and "The Water Supply", but the author is most at home in the upper stories and his treatment of atmospheric electricity, the ionosphere, ozone and meteors ("Throwing Stones at the Weather House") is especially good. Unusual also is his account of the organisation of synoptic forecasting in a meteorological office—"The Servants' Quarters"—for when looking at a weather map one is apt to forget, for example, the "comrade in Moscow stamping through the snow" to read his instruments. There is much sound sense if little enthusiasm in the short chapters on "Saws, Saints and Sages", "Controlling the Weather", and "Further Outlook—?"; the last chapter in fact is definitely pessimistic; but the warning is timely.

(2) Weather proverbs are many and varied; some are useless but others contain a grain of truth. Prof. Humphreys sets out to rescue the latter from their undesirable companions, and to clothe them in a garb of logic. The result is an attractive essay in popular science, though not everyone would agree that all the selections are justified, and a few of the explanations seem a little far-fetched. The belief that a grey morning sky betokens a fine day may be capable of explanation, but a 'grey' sky is presumably an overcast sky, and in Great Britain the observations of Spencer Russell have shown that an overcast sky at sunrise is about as likely to be followed by rain before sunset as is a red morning sky. One proverb with at least as much justification as the grey sky at morning has been omitted from the chosen company, namely:

"Rain before seven
Lift before eleven."

We should like to see more of these proverbs subjected to the test of observation. A few of them are probably true of North America, but will not bear transplanting to Great Britain. Some of the "paradoxes" of part 2 are rather forced, but a few provide interesting examples of the curious working of physical laws. On the whole, the selection, like that of the proverbs, is good, while there can be no two opinions about the excellence of the sixteen plates.

Spektroskopie
Von Prof. Dr. Karl Wilh. Meissner. (Sammlung Göschen, Band 1091.) Pp. 180. (Berlin und Leipzig: Walter de Gruyter und Co., 1935.) 1.62 gold marks.

THIS little book is not intended for spectroscopists, but rather for non-specialised students of physics who need a straightforward elementary account of spectroscopic principles and methods. The scope is wide, scarcely any major branch of the subject escaping at least brief notice, the presentation orderly and clear, and the diagrams astonishingly numerous in relation to the low price of the book. The emphasis is laid, on the whole, on the instrumental side of the subject, and the explanations of the various types of high-resolution spectroscope are particularly well done.

It is, in fact, just the right kind of book for an honours student of physics who wishes to read some German, for, though simple in style and in matter, it is yet sufficiently informative to be read for its own sake and not merely for reading practice.

Numerical Studies in Differential Equations

By Prof. H. Levy and E. A. Baggott. Vol. 1. Pp. viii+238. (London: Watts and Co., 1934.) 12*s*. 6*d*. net.

THE teaching of differential equations in English universities usually follows an unsatisfactory middle path. General theory is omitted as too difficult, while numerical methods are considered unworthy of notice. In consequence, the student is made acquainted with only a small number of special types of equation and is left to believe that nothing can be discovered about the solutions of other types. A reading of even the first two chapters of this book by Prof. Levy and Mr. Baggott would alter the outlook of many such students completely. The second chapter, on graphical methods of solution, would form an excellent addendum to a course in curve-tracing, the two together being used to illuminate wide tracts of algebra, geometry, and the calculus.

The main portion of the book is concerned with the numerical solutions of ordinary differential equations of the first and higher orders, consideration of partial differential equations being reserved for the second volume. Many methods, some well-known, some apparently new, are given and their degrees of accuracy are discussed and compared. It is impossible to estimate the value of these methods without long experience in their use, but they appear to be sufficient for most purposes and some of them are of considerable theoretical interest.

There are a few obscurities which might have been removed by careful revision, and a larger number of examples for practice might well have been included. These are minor criticisms, and detract but little from the value of a book which should be in the hands of all who are engaged in research in applied mathematics and of all who are interested in the improvement of mathematical teaching.

Faune de France

28: Diptères (Brachycères), (Muscidae Acalypterae et Scatophagidae). Par E. Séguy. (Fédération française des Sociétés naturelles: Office central de faunistique.) Pp. iii+832+27 plates. (Paris: Paul Lechevalier et fils, 1934.) 300 francs.

THIS systematic survey of the acalyptrate muscid flies testifies to the skill and industry of its author. Numerous keys in the form of tables, short clear descriptions with remarks on differential characters of the families, genera and species, and 903 text figures in addition to 27 plates facilitate, so far as is possible, the identification of these flies. Under each species is a note of the area of distribution and, where known, the period of occurrence of the imago. In those species, the larvæ of which are phytophagous or parasitic, the food-plant or host is stated. In nine pages is a summary of the bionomics of these lower muscids, and at the end of the volume are alphabetical lists of their animal hosts, with their respective parasites and commensals, and of the plants and their respective muscid parasites. A good bibliography and systematic index complete this very satisfactory work.

Wild Flowers of the Great Dominions of the British Empire

By The Lady Rockley. Pp. xii+380+32 plates. (London: Macmillan and Co., Ltd., 1935.) 16*s*. net.

THE non-botanical traveller, who is unable to use a technical flora, often feels in need of a book which will help him to appreciate the vegetation of the various lands he visits and which will indicate what floral treasures are especially worth his notice in particular areas. Lady Rockley, in the present volume has given the traveller in the British Dominions just such a guide, and her book will undoubtedly appeal to a large public of flower-lovers.

The countries dealt with include Canada and Newfoundland, Australia, New Zealand, South Africa, Rhodesia and Kenya. An immense amount of information has been packed into Lady Rockley's attractively written pages, and the coloured illustrations, many of them painted by the author during her travels, with no thought of publication, add greatly to the value of the volume.

Birth Control and its Opponents

By Frank W. White. Pp. xi+164. (London: John Bale, Sons and Danielsson, Ltd., 1935.) 3*s*. 6*d*. net.

IN this little book, the facts of population and over-population, and the wastage of human life that results under uncontrolled conditions of mass reproduction, are first marshalled. The regulation of births and limitation of population by artificial methods are then detailed, and the benefits likely to arise therefrom stated. Finally, the arguments of the opposition to artificial methods for the control of pregnancy are set out and examined.

No better brief and popular summary of the subject of birth control could be found than is given here, and as Lord Horder says in his foreword, Dr. White deals patiently and convincingly with the arguments that are advanced against it by a small section of the community. It may be hoped that a growing public opinion will in time convert religious authority, from which the chief opposition at present emanates.

R. T. H.

A Flower Book for the Pocket

By Prof. Macgregor Skene. Pp. 380. (London: Oxford University Press, 1935.) 7*s*. 6*d*. net.

THIS pocket-book is meant for the layman and also as a first 'flora' for use in schools. 501 flowering plants are illustrated in coloured plates, most of which are reproductions of the paintings by the late Miss C. G. Trower. The rest, together with 28 black and white drawings of grasses, are the work of Miss Ruth Weston. To our knowledge, there is no other book at the price which is so profusely and well illustrated. So far as is possible, technical terms have been avoided. The key includes all British families, and the sequence follows that of the standard British 'floras'. It has been compiled by Prof. Macgregor Skene. Thus, the book has the stamp of authority, is well produced and, unlike many 'floras', is easy to follow. This, together with its low price, should ensure the book of the success that it clearly deserves.

Some Aspects of the Polar Regions*

By Prof. F. Debenham

THERE is now a vast literature of the polar regions, both north and south, but the proportion of those books and papers which deal with the subject on a broad basis is very small, and is certainly not easily accessible. In many of these books we are invited to conjure up the sensations of the polar explorer, to feel his frost-bites, to savour his pemmican, to glory in his pack-ice and his glaciers, even to die his death. Not the least part of our interest in polar work is due to these invitations so graphically offered to us in text and illustration. Much more rare is it to find a polar explorer viewing his territory as a whole, and trying to fit it into the scheme of the world in general. In a word, we are rather encouraged to regard the polar regions as places apart, extraneous to the real comity of the world. We will first consider the kind of value of the polar regions which appeals most quickly to the public.

Trade and Trade Routes

There is little need to sketch the history of man's attempts to achieve economic gain from the polar regions. From the days when Martin Frobisher attempted to find a quick route westwards to the Spice Islands *via* the North-West, and Barents a similar route eastward, down to more recent times when, though the routes had lost value, the products of hunting, fishing and mining attracted venturers with similar motives, the chief aim of promoters of polar expeditions has been one of ultimate gain. It is true that many of the leaders of the expeditions had little care for the commercial side, but the money that sent them forth was, in the greater number of cases, put out in the time-honoured hope of all ages that it would bring in interest in some form or another.

There is certainly such a thing as the romance of commerce in the North, for most of its industries have something peculiar and unusual about them. We may instance the cryolite mines of Ivigtut in Greenland—a strange mineral found in quantity nowhere else in the world, which however is almost essential to the large-scale production of aluminium. Again, until recently a large proportion of the ivory for use in northern China did not come from the present-day elephants of the rain forest belt of Asia, but from the mammoths of primeval times the tusks of which lay for many thousands of years buried in the mud of the great Siberian rivers flowing into the Arctic Ocean.

Romantic or not, the story of Arctic trade has a grim and melancholy side, in that several of its most promising ventures have died a slow and painful death by reason of the cupidity of man and his unwillingness to co-operate either to preserve life or even to preserve it sufficiently for his own benefit. The history of the whaling industry in the Arctic is an instance of this incapacity of man to co-operate in taking the most common-sense measures to cherish a valuable industry. There is every reason to hope that the day of non-co-operation has passed and that a similar fate to whaling in the Antarctic will not take place, for it is probably common knowledge that many bodies, in which we may include the League of Nations, the Norwegian whalers themselves and the "Discovery" Committee of the British Government, are at work in their various spheres to prevent any extermination of the southern whales, and at the same time to regularise an industry which, even in these days of synthetic materials, still has its vital uses to man. How large that industry now is may be gathered from the fact that the annual catch of whales in the southern seas is about 20,000: how mindful it now is of its own future may be seen from the fact that whereas the average whale used to provide only 60 or 70 barrels of oil, it is now made to yield nearly 120 barrels of oil besides other products.

These products of hunting, fishing and mining were the natural resources of the North and were the first to be exploited, but quite recently a new factor in the commercial aspect of the North has come to the forefront. With the progress of long-distance aviation and the simple application of the principle of great-circle navigation, the idea of using these northern latitudes for passenger and even freight routes in the air has become not only prominent but also almost insistent.

Owing to the misleading projections on which most of our maps are constructed, it is not usually recognised that the most direct route between, say, Berlin and Montreal, or Glasgow and Winnipeg, is over Greenland, but it is so. It seems to be only a matter of time and the inevitable improvement of aeroplanes before some use is made of a route which was first investigated as to conditions by the Watkins Expedition of 1930.

Summing up this economic aspect of the polar regions, the warning may be given that even now,

* From the presidential address to Section E (Geography) of the British Association, delivered at Norwich on September 5.

as in the past, there is a tendency to ascribe potential wealth merely on account of the existence of land masses. Indeed, even explorers, who should have known better, have been heard to speak glibly of the untapped mineral resources of the polar lands, neglecting to tell their public that though these resources undoubtedly exist, they are for the most part covered by thick ice sheets or rendered inaccessible by topography, or climate, or both. Quite a brief calculation, for example, would show that the proportion of the Antarctic continent available to the prospector and miner is to the total land mass in somewhat the same proportion as the area of the city of Norwich is to the whole of England.

Although the land can have little value in the Antarctic there is, strangely enough, a natural resource in the air which, however fantastic it may appear to us, may yet have a substantial interest for our descendants. It is a truism of science that we draw practically all our sources of power from the sun, either indirectly in the form of coal and oil, or directly in the form of water-power, in which the sun by evaporation has raised water to a height from which gravity, suitably used, returns power to us. Now, although water is one of the things of which there is a great scarcity in the polar regions, and the movement of ice masses can scarcely be handled by engineers, yet meteorological processes are doing the same thing for air, raising masses of air in one area which sink down in another, and so provide a source of power less tangible but just as real as that of water in a highland lake. The persistence, the strength and the frequency of the Antarctic blizzards compels anyone who has experienced them to feel that here is a vast source of power as yet untapped. May we be permitted to forecast that some day the miseries of the storm-bound parties of Mawson's expedition, when for a whole year the wind averaged gale force, may be atoned for by our descendants making use of this power when coal is scarce and oil exhausted, while all the water-power in the temperate regions is fully harnessed? Compare the power in the well-known falls of Niagara, about 6,000 tons of water falling per second, with the power in the little-known Adélie Land, where an air river of at least 50 miles in width and probably some hundreds of feet in depth is moving outwards from the plateau at an average velocity of 50 miles per hour, or about 70 ft. per second for most of the year.

The Poles as Sanatoria

We pass now from the economic aspect of our subject to some others which have less appeal to the man in the street, but which must never be omitted in any consideration of a region by geographer.

The consideration of the polar regions a holiday resort for the citizens of crowded la leads us naturally to a far greater value wh has as yet scarcely been considered by civilisati a value which indeed may yet prove to be mo worthy of study than all those we have so fa mentioned. It is reasonable to suppose that whe some far-travelled medical man comes to write book on the geography of diseases, we shall b able to come by a clear idea of where health is bes to be sought. The ordinary geographer would however, even now be able to make something o an essay on the distribution of healthiness over the world. Leaving out cities as unnatural, or at least unhealthy aggregations of humans, he would at once say that, on the whole, the most unhealthy parts of the world are in the tropics, though he would have to have a special category for tropical and oceanic islands, which as a rule are decidedly healthy. He would, if he were wise, consider that the steppe deserts are healthy zones; but probably he would decide that the temperate zone as a whole, provided it is not too far from the sea, is the healthiest belt of the world for man. It is almost certain that he would entirely forget tha the polar regions are definitely the most healthy segments of the earth's surface, for the simple reason that the ordinary disease-bearers, whether they be rodents or insects or minute bacilli, find the conditions either impossible for existence or inhibitive.

But we are not concerned here so much with the healthiness of the zone as with its value from a remedial point of view, for we are certainly not going to migrate in millions to the Arctic just because we cannot there contract the diseases of our own lands. But what we may well pay attention to is the corollary to that healthiness, namely that many, though not all, of the diseases contracted in temperate climates can be cured by residence in the polar regions.

I am aware that it is more than dangerous, indeed provocative in the highest degree, for anyone outside the medical faculty to say how far special diseases are curable by residence in a pure air and a cold one. It seems, however, from the experience of sanatoria in the Alps, etc., that it is the sufferers from pulmonary diseases who are most likely to get benefit from such residence. The question will at once be asked as to what the polar regions can supply which is not already obtainable, say, in the Alps. For an answer to this question we must look to the medical men; but it does seem likely that residence in a vast territory free from germs or the conditions for their transport must, *prima facie*, be better than

esidence in an alpine region which is surrounded by, and is merely above, zones teeming with possibilities of disease. If this thesis is correct, and it is one which a small period of research could easily confirm or refute, then surely we are neglecting an aspect of the polar regions which is of major importance to mankind, more valuable than all the industries they will ever support.

To test the value of the suggestion there is needed research and experiment, most appropriately to be carried out under the auspices of one of those international bodies such as the Rockefeller Foundation, which has already done so much for remedial medicine. For assistance in carrying out this research there is needed the sympathy of Governments, especially that of Norway, in the care of which is the most promising territory in the Arctic for that purpose, namely, Svalbard or Spitsbergen.

Let us remember too, before we allow hands of horror to be raised at the expense of such research, that in the past sums of money have been spent in Spitsbergen itself for the erection of an airship hangar and provision of the airship itself for a few hours' flight to the Pole, which would be sufficient to erect a hospital and run it for many years in an experiment which might be of permanent value to the world. We must be properly cautious as to results, but at the same time let us preserve our sense of proportion in the value to man of how we spend money in the polar regions. It is almost lamentable to consider the sums of money which have been spent in what may be understood by the term of 'stunt expeditions' and place those sums in contrast to the difficulty in raising money for such an object as this.

World Meteorology

We may now turn to yet another aspect of the polar regions, namely, the value to the scientific worker, both pure and applied, of the phenomena which are peculiar to these regions—phenomena well known to exist but the study of which is still in its early stages.

No doubt each science will claim the chief value of these phenomena for itself, but it is without any particular bias to one or the other that I should venture to place in the first rank the subject of meteorology as likely in the future to gain most by a prolonged and more intensive study in high latitudes.

We have spoken of the more or less permanent blizzards on parts of the Antarctic continent, and we ourselves live under the intermittent threat of depressions over Iceland. We can therefore, without much imagination, see that even if our weather is not actually manufactured at the polar ends of the world, it is profoundly affected by them. Meteorologists themselves have long been aware of this, and in two successive onslaughts, namely, in 1882 and in 1932, a determined effort was made to collect data simultaneously and widely within the precincts of the Arctic. The conclusions which have been drawn from these results are, as yet, scarcely in full circulation, but few meteorologists do not sigh for more and more data from the polar regions.

The phenomena of magnetism and aurora, which are somewhat akin to those of meteorology in that they occur in the atmosphere, are also best studied in high latitudes, where, too, the most promising investigations of the ionosphere seem to be likely.

Geology

When we come to the more earthly sciences, the immediate value to mankind is perhaps less evident. In the science of geology, for example, especially in its branch of tectonics, we cannot afford to do without close investigation of two segments of the earth comprising together nearly one tenth of the surface of the globe, and indeed the structure of the earth must become the more interesting the nearer one gets to its axis of rotation. The geologist has a hard task in lands where the rocks are usually buried beneath ice-caps, and has to be more than usually ready with the inspired guess than in other parts of the world.

In the Antarctic in particular, the highest of all continents and the most closely hidden, there are obviously to be found keys to some of the major problems of earth structure. We may instance only one which, no doubt, is occupying the attention of the geologists of the British Graham Land Expedition at the present moment, an expedition which hopes to press far to the south of the Archipelago where they are wintering, and to determine why and where the folded ranges of South America and Graham Land merge into or butt against the faulted escarpments of the Australian sector of the Antarctic.

It is in these larger problems of geology that the polar geologist can give most assistance to science. It is not long since the papers, in America at all events, were full of the discovery of coal beds by Admiral Byrd's geologist within 300 miles of the South Pole, and it was interesting to see that this discovery, which however was originally made by the Shackleton party in 1908, moved the Press public to exclamations of wonder that such things could be. Nevertheless the great controversies of whether the Poles have shifted in the past, and whether the continents are drifting, must draw their best evidence, both for and against, near the axis of the earth.

There has recently been published a fresh determination of the position of Sabine Island on the coast of north-east Greenland which tends to show that there is a definite westerly drift of some metres a year. Similar observations of Jan Mayen are even more startling. For these and other reasons, therefore, the geophysicist, whom we may call the mathematical cousin of the geologist, must keep his attention on the polar lands.

In the biological sciences also there are major problems to which the data of high latitudes alone can give the key, such as the drift of oceanic waters and the movements of plankton and their associated salts. The biologists, however, are already active in these investigations and need no spur to action. The many-sided character of the work of the "Discovery" Committee in this branch, over all the waters of the Antarctic ocean, is evidence of how carefully work on this aspect of the polar regions is being carried out.

The Spirit of Exploration

Lastly, I would consider yet another aspect of the polar regions, one which is perhaps more psychological than geographical, namely, their value as an outlet to that spirit of adventure and urge for exploration which has always been an attribute of man, and which will not diminish, however small the world may grow. It is a spirit which is at work equally in the small child climbing the apple tree, the schoolboy exploring his own small horizon, the undergraduate forming alp clubs to scale the peaks of his own college, and city clerk spending his week-ends living dang ously in sailing dinghy or on motor-bicycle.

In all of these there is a curious combination an urge to test one's abilities and yet a desire f a secondary and more useful object in the de itself, and this dual purpose is particularly evide in most of the young men who come to the Sco Polar Research Institute in Cambridge seeki ways in which to visit the Arctic.

Looking over the files of the geographica journals of the past few years, it is possible to se how many young men turn annually to the Arcti to satisfy their need for an outlet. If we includ the official expeditions of Governments such a that of the Soviet, we shall find that every summe more than fifty groups of investigators go to the Arctic and, were it less expensive, the number would easily be trebled. Only a few of these groups go for purely scientific work, and still fewer for hunting alone. They are, in fact, as a rule imbued chiefly with a desire to see strange places and endure strange things, and only in a secondary way to bring back useful results. There has been of recent years a happy tendency for these groups to go and come back without undue fuss and publicity. I would suggest that this use of the Arctic as an outlet to a healthy and laudable desire is one which should not be left out of any assessment of values even though it must necessarily apply only to a small number of people.

Problems of Plant Pathology

THE presidential address of Mr. F. T. Brooks to Section K (Botany) of the British Association delivered at Norwich on September 9 began in very pleasing vein by describing some of the outstanding contributions to botany made in East Anglia, wherein Norwich is an ancient and important city. It is fitting that upon such an auspicious occasion, the president of the Section should remind his audience of the deep roots of botanical lore in Great Britain—roots which go back to the enthusiasm of the ardent amateur. One heard the names of W. H. Burrell, W. A. Nicholson and Dr. C. B. Plowright coupled, in the recital of botanical progress in Norfolk, with more professional workers such as Dr. M. C. Cooke, Sir W. J. Hooker, Prof. F. W. Oliver, Prof. E. J. Salisbury, and many others.

The title of the address was "Some Aspects of Plant Pathology", and after showing that Norfolk farmers were among the first to realise the damage caused by disease, Mr. Brooks continued with a discussion of disease control by the use of resistant varieties of crop plants. The bad effect of several wilt diseases, the leaf-curl disease of cotton, and black rust of wheat can now be controlled with considerable success by planting new varieties with resistant qualities, but it seems very unlikely that all diseases will be amenable to control by this method. New diseases are continually appearing, parasitic fungi are amongst the most variable of living organisms, and the capacity for disease resistance in the host is very much in the nature of a mutation. The nicely-adjusted equilibrium between parasite and host can be upset when the latter mutates towards resistance, but the fungus can also vary, to give a new physiological form capable of attacking the host mutant. Thus the biological race for

supremacy continues, and leads the plant pathologist to investigate further principles of control. Moreover, although the use of resistant host varieties is the most care-free method of disease control, it is not always the most efficacious. Bunt in wheat, for example, may be totally eliminated by simple fungicidal treatment of the seed before sowing, and infection of fruit trees with *Stereum purpureum* can be greatly minimised if the fungus is merely prevented from fructifying in and near the orchard. Such simple methods of plant hygiene should be part of the routine of every good gardener or farmer.

The ecological study of fungi is in its infancy, but the effect of climate on some diseases has been investigated. Prof. L. R. Jones and his colleagues at the Department of Plant Pathology, University of Wisconsin, have inquired into the effect of soil temperature upon disease incidence. Such parasites as *Urocystis cepulae*, for example, cannot infect the onion plant when the soil temperature rises above 29° C.[1]. Reinking[2] has shown that differing types of soil may play a controlling part in fungal attack, for the wilt disease of bananas in Central America is much more severe on sandy soils than on clay. High humidity may also inhibit parasitic attack, for the pink disease of rubber in Malaya only appears in the regions of highest rainfall. It seems likely that in the near future it may be possible, by studying weather conditions, to advise growers of the appropriate times to spray potatoes and vines with *protective* fungicides against blight (*Phytophthora infestans*) and downy mildew (*Plasmopara viticola*) respectively. Such treatment, if performed thoroughly and as a matter of routine by all growers would, in all probability, entirely prevent the development of either disease.

The physiology of parasitism is now fairly well understood. The Tulasne brothers, de Bary, Brefeld, and Marshall Ward carried out much pioneer work, and the subject has been further interpreted by Prof. V. H. Blackman in more recent years. Mr. Brooks himself, in his specialist work on *Stereum purpureum*, has shown that the characteristic silvering of fruit tree foliage can be produced by injecting the stem of a healthy plant with non-living extracts of the fungus.

Our ancestors must have felt despondent and impotent when a sudden attack of black rust spread amongst their wheat, or when blight devastated their potatoes. We can scarcely wonder that they used the term 'magic' to account for such epidemics. Yet the glamour of magic is far surpassed by the fascinating results of investigations into the cause of such apparently spontaneous outbreaks. Mr. Brooks chose a sufficiently sensational example from the work of Mehta[3] in the lowlands of northern India. Uredospores of the fungus *Puccinia graminis* cannot withstand the very high temperatures of the plains in summer, yet the parasite appears year after year. The usual alternative host, *Berberis vulgaris*, here plays no part in the life-history. Infection comes each year from stray wheat plants growing above a height of 4,000 ft. in the Himalayas. Summer temperatures there are relatively moderate, and uredospores multiply normally, infecting the wheat crop of the hills during November and December. There is thus a continual source of spores, some of which are carried many hundreds of miles to the plains, by the prevailing north-westerly winds.

Research into physiological forms of parasitic fungi has been very active during the past ten years. More than a hundred such forms of *Puccinia graminis* are now known. The structure of each form is identical with that of all its fellows, but its host relations are different. Many other species of fungi have numerous physiological or biological forms, and it is obvious that the plant breeder is confronted by a very difficult task in his search for new host varieties which would be disease-resistant. The range of physiological forms does not seem to be standard, for types of *Puccinia triticina* and *P. glumarum* have been found at Cambridge, which do not appear on the Continent, and vice versa. This multiplicity of strains may even include non-pathogenic forms, as happens in the fungus *Fusarium cubense*, causing wilt disease of the banana[4]. Physiological forms may have arisen as a result of hybridisation, but some must also have arisen as gene mutants, since they appear in fungi such as *Puccinia glumarum* which are now, in all probability, entirely asexual. Mr. Brooks discountenances the idea of a 'bridging species', originally introduced by Marshall Ward to mark a host plant which was susceptible to distinct physiological strains of fungi from two further hosts which would not inter-infect. The bridging species would 'educate' the strains to infect their mutual hosts. A simpler explanation of Marshall Ward's results seems to lie in the large number of physiological forms which are now known to exist.

The interaction of two or more fungi upon one another has a profound influence on plant pathology. A rotting log provides material for a succession of fungi, one after another, and each with its own particular taste for wood at a certain stage of decomposition. Similarly, a wheat plant normally resistant to *Puccinia glumarum* becomes susceptible to that fungus if attacked also by bunt (*Tilletia Caries*). More severe attacks of citrus trees follow infection by *Diplodia natalensis* and *Colletotrichum gloeosporioides* together than is the case with either organism alone[5].

Two organisms may also act in antagonism to one another. Mr. Brooks's experiments on various species of *Stereum* show that oak wood attacked by *S. hirsutum* is not a suitable habitat for the more harmful *S. purpureum*. Fawcett and Lee[6] could not obtain any effect on the walnut tree by inoculating it with two parasitic fungi, each of proved pathogenicity. Millard and Taylor[7] also found that the organism causing common scab of potatoes lives in antagonism with a harmless species. The latter can be stimulated by the addition of organic matter to the soil, thus controlling the disease. Weindling[8] found that *Trichoderma lignorum*, a saprophytic fungus, produces a substance which is toxic to the hyphæ of *Rhizoctonia solani*, and, indeed, the depredations of the latter can be curtailed if spores of *T. lignorum* are added to the soil. The old saying "Set a thief to catch a thief" seems to be justified even in the realm of plant pathology.

Many disorders of plants appear for which no definite causal agent can be demonstrated. Certain crops, for example, do not make good growth if the element boron is absent from the soil. Heart-rot of sugar beet and mangolds seems to be due to such lack. Manganese deficiency is responsible for grey leaf or grey-speck of oats, whilst insufficient sulphur produces a serious disease of tea bushes in Nyasaland[9]. Several diseases of apples during storage are due to inordinately large amounts of carbon dioxide in the atmosphere. Brown heart is such a disease which can be overcome entirely by proper ventilation[10]. Injury by frost can also produce symptoms which are similar to those caused by some fungi. Canker of the larch tree, for example, may be caused either by frost, or by the depredations of *Dasyscypha*[11], both of which, in all probability, kill groups of active cambium cells.

Many of the researches outlined in Mr. Brooks's address have added to general botanical knowledge. It is often necessary for the pathologist to study a new phase of plant physiology, and alternatively, the physiologist can supply knowledge which is useful to the pathologist. The address was pre-eminently what we have come to desire of a sectional president—a point of view, emanating from his own specialist knowledge, and linking up with other branches comprised within his Section; the orientation of scattered facts into one harmonious whole.

Speed*

By Prof. B. Melvill Jones

THE factors which have limited speed in the past can be grouped under two main heads, which may be roughly described by the words *Track* and *Power*. To move rapidly over the ground a smooth track is necessary in order to prevent the vehicle from bumping itself to pieces and from overturning, while power is required to overcome the internal friction of the mechanism and the head resistance which must always oppose motion, until we can arrange to do our travelling entirely outside the earth's atmosphere. These two factors, track and power, have alternately imposed limits on the speed of travel, one coming into operation whenever the other was temporarily removed.

The power to fly through the air at a height sufficient to be clear of the irregular air flow near the ground has at last disposed of the track problem as a factor limiting speed. For although the aeroplane has to lay its own track, in the sense that it has to expend power in doing something to the air in order to keep itself from falling, that power becomes continually less the greater the speed of flight and, of itself, is incapable of placing any limit on speed.

In the early days of flying, we were unable to separate the power essentially required for support—for track laying as we may describe it—from the power required merely to drag the aeroplane through the air. That this can now be done is due to the work of Prof. L. Prandtl, which was itself founded on some earlier work of that amazing mechanical genius, Dr. F. W. Lanchester. Looking back from our present point of view, Lanchester's insight into this very difficult problem seems almost miraculous, but he did not put his ideas into a form which appealed to the conventional man of science, and it was not until

* From a Friday evening discourse delivered before the Royal Institution on March 22.

they had been developed and given greater precision by Prandtl that they received any wide recognition.

The Lanchester-Prandtl calculations, as they are now called, may become very complicated, but the ideas behind them are not difficult to grasp. Everyone is familiar with the idea that when a body is projected suddenly in any direction the apparatus which does the projecting experiences a recoil. The rocket, for example, obtains the lifting force which sends it up by generating gas within itself and continually projecting the gas downwards, so that there is a continuous recoil which drives it upwards. The aeroplane obtains the lift which supports it in a manner similar to the rocket, except that it does not itself generate the gas which it projects downwards, but uses the air through which it is passing. The wings, driven through the air in an attitude slightly inclined to the direction in which they are moving, force down the air directly below them and suck down the air immediately above them, and in so doing experience the continuous recoil which keeps the aeroplane from falling. The air, however, forms a continuous medium around the aeroplane, and a downward current in one part implies an upward current in other parts, with outward cross currents below to relieve the congestion there, and inward cross currents above to fill the partial vacuum which would otherwise be formed.

These air movements can be calculated and, at the moment when the aeroplane is passing, they take the form shown in Fig. 1, where the aeroplane is seen from behind passing through the vertical

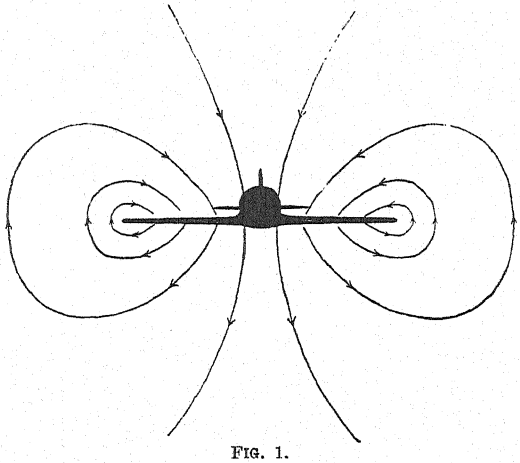

FIG. 1.

plane represented by the paper. The curved lines show the directions of flow; the distances between them being inversely proportional to the speed of flow. As soon as the aeroplane has passed, the flow pattern which is left behind begins to modify itself and ultimately takes the form shown in Fig. 2, which is simply the system of flow known as the *vortex pair*. These vortices, which are generally described as the *trailing vortices*, because they trail behind the aeroplane, remain in the air for several minutes after the aeroplane has passed, and are the cause of the bump which one feels on flying through the track of another aeroplane. It is by continually setting these air whirls, or vortices,

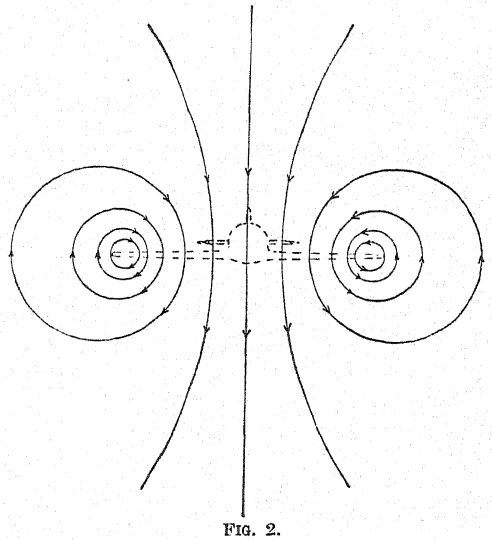

FIG. 2.

into motion, that the aeroplane supports itself, and it is because these whirls have to be continually created that power must be expended to obtain support. In effect, therefore, the aeroplane has to use some of its available power to create its own track, which is left behind in the air after it has passed.

The Lanchester-Prandtl calculations enable the power expended merely in supporting an aeroplane to be calculated with considerable accuracy; they show, for example, that the power required for this purpose, for every thousand pounds of weight of a modern civil transport aeroplane, ranges from about eight horse-power at one hundred miles per hour, to four horse-power at two hundred miles per hour, and is still less at higher speeds. Since the power actually available in civil aircraft of the present day, after allowing for losses in the screw propulsion, is of the order 60–70 horse-power per thousand pounds weight, it is clear that, although the aeroplane must pay for the elimination of the track problem by the expenditure of extra power, the amount of this extra power and the way in which it varies with change of speed are such as to place no final limits upon speed.

Having reached this conclusion, we are free to turn our whole attention to the remaining factor which does, and probably always will, limit speed: the resistance which has to be overcome merely to drag the aeroplane through the air.

Anyone who has ridden a bicycle must know that the air can exert a very considerable resistance to the passage of a man through it, even when the speed is so low as 15–20 miles per hour. Since the power required to overcome this resistance increases about eight-fold every time the speed is doubled, it is at once apparent that very great powers may be required at high speeds. The following table shows approximately the power required to push a man in a sitting posture through the air near the ground at various speeds.

Miles per hour	*Horse-power*
10	1/25
20	1/3
50	5
100	40
200	320
300	1,100
400	2,600

Such figures make it clear that unless head resistance can be very considerably reduced below these figures, economical transport at high speeds is impossible. Everyone nowadays knows that this reduction can be made by what is usually called *streamlining*, and our next task therefore must be to consider why streamlining is so effective in reducing head resistance.

We have now to begin from the point of view of the mathematicians who, some fifty years or more ago, studied the basic problems of fluid motion. They observed that water and air are very slippery substances, and they conceived the idea of studying an ideal fluid which they imagined to be absolutely slippery. Almost at once they reached the astonishing conclusion that solids of any shape whatever would be expected to move through such a fluid—if it could exist—without any resistance whatever. Impressed by this paradox they, for the most part, gave up any attempt to apply their theory to practical purposes; but fortunately for us this did not in any way damp their enthusiasm for the subject itself, which they pursued, one must suppose, for the sheer love of the game, or perhaps with the idea of providing problems for university examinations. But whatever the impulse behind their work, Providence has, as usual, seen to it that their efforts were not wasted, for they laid the foundations of the science which has enabled us to seek for and obtain the very great reductions of resistance which are essential for high speed transport. For it so happens that when bodies are given the now familiar streamline shapes, the flow around them takes almost exactly the form imagined by the mathematicians for their ideal fluid, and the pressures exerted by the fluid on the surface of the body are so nearly the same as those given by the theory, that their net effect in resisting motion is, as the theory suggests, practically zero. Fig. 3 shows the theoretical flow and pressure distribution of the ideal fluid about a good streamline body; the real flow and pressure distribution for this body would be almost indistinguishable from these theoretical values.

Why then does a perfect streamline shape experience any resistance at all to motion? It is because the air, unlike the ideally slippery fluid, cannot actually slip over the body, but must exert a very slight dragging force along its surface, and it is this dragging force, or *skin friction* as it is called, which alone offers any appreciable resistance to the passage through the air of the best streamline shapes. Here then is a curious situation, for while everyday experience makes it seem 'natural' for us to suppose that the air should strongly resist the rapid passage of bodies through it, the difficulty, when the matter is approached

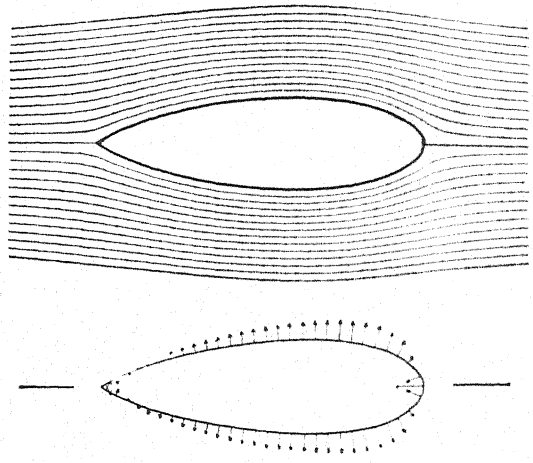

FIG. 3.

from the theoretical end, is to explain why the resistance of any body is greater than the exceedingly small force which can be applied by the mere rubbing of the air over its surface. The wide gulf between the two points of view is shown by the fact that at the speed of modern aerial transport, the resistance of a badly shaped body may be as much as fifty times greater than that of a good streamline body of the same frontal area.

Now we have to find an explanation for the high resistances of unstreamlined bodies. This is due to a curious feature in the behaviour of the air flow, which would be impossible in the ideally slippery fluid; for the real air streams have the power of leaving a curved surface and forming pockets of what is called *dead air* behind the bodies. Within these pockets the pressure is low and so the bodies are, as it were, sucked backwards. On closing up behind these pockets the air stream becomes very turbulent and full of regular or irregular eddies which continually carry away the energy corresponding to that expended in moving the body against the high resistance.

(To be continued.)

Nuclear Physics

THE British Association discussion at Norwich on nuclear physics on September 5 was opened by Lord Rutherford. After a review of progress resulting from the application of high voltages to nuclear transmutation, he passed on to discuss the rapid development of our knowledge of artificial radioactivity and in particular the production of such radioactivity by neutron bombardment. Neutrons, being uncharged, penetrate the heaviest nuclei without difficulty, and radioactive isotopes of the great majority of the elements have already been discovered. The effectiveness of neutrons in producing some types of transmutation is increased largely by slowing them down by passage through paraffin, water or other substances containing hydrogen, the neutrons losing energy by collision with the protons. By slowing them down in this way to thermal velocities, their adsorption by boron is increased 350 times, by cadmium 3,000 times, and by gadolinium 30,000 times, the effective cross-section for capture then being of the order of 10^{-20} sq. cm. A demonstration that neutrons actually obtain thermal velocities is afforded by slowing them down in paraffin wax cooled to liquid air or liquid hydrogen temperatures. This extra cooling reduces the velocity still further, and an increase in the efficiency of disintegration has been observed by P. B. Moon and others.

Lord Rutherford considers that it would be of interest to see whether neutrons reach the upper layers of the atmosphere in appreciable numbers, and whether they can account for any of the cosmic ray phenomena. He hopes that future expeditions to the stratosphere will include apparatus for the detection of neutrons.

He passed next to discuss the new radioactive isotopes. These isotopes must exist in the sun or other hot stars where a natural nuclear bombardment must be constantly proceeding. They would therefore exist in the substance of the earth when it was first flung off from the sun, but in the course of time they would progressively disappear, only those with the longest lives such as radium with its unstable products remaining.

Dr. C. D. Ellis stressed the importance of the accurate measurement of the energies of electrons, γ-rays and protons emitted in related transmutations. Thus aluminium bombarded by α-particles can change into Si^{30} and a proton, or to Si^{30}, a neutron and a positron. An accurate measurement of the kinetic energies in the two alternative modes of transmutation would show whether in all cases the energy liberated in the positron emission is given by the maximum positron energy. It appears that many of the measurements made hitherto were quite unreliable, estimates of maximum positron energies varying by factors so large as two. Dr. Ellis expressed the hope that the exciting work of discovering new radioactive elements would shortly give way to more precise work.

A similar point was raised by Dr. J. D. Cockcroft. It is well known that carbon bombarded by deuterons can either give C^{13} with the emission of a proton or through the production of radionitrogen to C^{13}, a positron and a neutron. The kinetic energy release in the proton reaction has been measured carefully, and is 2·7 million volts. The total kinetic energy available for neutron and positron should thus be only 1·3 million volts. The maximum energy of the positrons on the other hand is at least 1·4 million volts, whilst the neutrons must possess some kinetic energy. A way out of the difficulty might be found by the discovery of other modes of energy liberation in the proton reaction although strong theoretical arguments have been advanced against the possibility of such other modes.

Dr. Cockcroft referred also to the properties of the new radioactive isotopes produced by proton and deuteron bombardment. Radioactive isotopes of lithium and boron have been discovered emitting electrons up to 11 million volts energies. Radiosodium which emits penetrating γ-rays can be produced by voltages so low as 500 kilovolts, but a 10-hour bombardment of a rock salt crystal with 10 microamps will produce a source emitting only 2,000 electrons per second, whereas an increase of voltage to 1·7 million increases the yield by a factor of 10,000. Prof. Lawrence hopes by advances in technique to increase the yield by a further factor of 1,000, and so to produce in a day a source of the same order of activity as a gram of radium. Prof. Lawrence considers that such sources might have great importance in biological work.

Dr. M. L. Oliphant showed how the accurate measurement of the kinetic energy changes in nuclear transmutations has led to a revision of the scale of nuclear masses. Until recently, the mass spectrograph data have been accepted without question, but several serious discrepancies have forced a reconsideration of the position. The mass of Be^{9} has caused the greatest difficulty, for on Aston's and Bainbridge's figures it should be able to disintegrate spontaneously into 2 α-particles and a neutron. It appeared that all

the difficulties were removed by the assumption that a small error had been made in determining the mass of helium relative to oxygen. Since most of the masses were measured in terms of helium, a complete revision of the mass scale necessarily followed. Dr. Aston has since repeated his mass spectrograph measurements using the more accurate brackets now possible with the use of deuterium, and has confirmed that revision was necessary.

Mr. M. Goldhaber reported the experiment of Dr. J. Chadwick and himself on the γ-ray disintegration of the deuteron. The neutrons resulting from the transmutation have been detected by their action in disintegrating lithium ; the proton energies have been estimated at 240 kilovolts using radium γ-rays.

Dr. N. Feather reported a more accurate determination of this energy by the use of a Wilson chamber filled with 'heavy methane'. 40 proton tracks were measured, the proton energy being about 180 kilovolts. The distribution of tracks was similar to that expected for a photo-electric effect. The new work requires a proton mass of 1·0086 on the revised scale.

Dr. P. B. Moon demonstrated the production of induced radioactivity by neutrons, and in particular showed how enormously the effect with rhodium is increased by slowing down the neutrons by paraffin wax.

News and Views

Demonstration of Firewalking

A DEMONSTRATION of firewalking was given by an Indian, Kuda Bux, before members of the University of London Council for Psychical Research and other men of science at Carshalton, on September 17. The fire was contained in two trenches about 12 ft. long, 6 ft. wide and 8 in. deep. Barefooted, Kuda Bux walked along the trenches twice, and his feet made contact with the burning embers for some five seconds each time. Prof. C. A. Pannett of St. Mary's Hospital sends us the following account of his observations : "Kuda Bux is physically of the typical, slightly built, Indian type. The soles of his feet present no unusual features. The skin is not callous but soft, as the skin of so many individuals who walk barefoot. The feet felt cold to the hand, and a skin thermometer registered 93·2° F. This was about twenty minutes before the attempt, during which time the performer walked about the lawn. A five-eighths inch square of zinc oxide plaster was attached to the sole of the right foot. The skin of the feet was very dry. The feet were washed and dried carefully about fifteen minutes before the walk. After the steps had been taken, with a delay of perhaps ten seconds, the temperature of the soles of the feet was again taken. It was now 93° F. There was no sign of burning of the skin.

"AT the conclusion of the performance, after Kuda Bux had walked twice over the pit, an interval of perhaps forty minutes having elapsed, the feet were again examined. By careful scrutiny could be seen here and there the whitened appearance of the skin which occurs when the very surface of the epithelium is scorched without blistering. Yet with the pigmentation present it was very difficult to be positive of this. There were no signs of hyperæmia or blistering. The patch of plaster was quite unharmed, except that the fluff of the cotton basis at the cut edge looked very slightly scorched. If this were so, these cotton fibres must have reached a temperature approaching 120° C. Mr. Digby Moynagh, who had made an attempt to carry out a firewalk ten days previously, made a second one. The soles of his feet had a number of blisters on them, which were in the healing stage. After two steps he acquired new blisters. The soles of his feet were noticeably moister than those of the Indian, and this factor may be of importance, because at one place the dampness had caused a piece of the charcoal to adhere. Underneath it a burn occurred. Mr. Maurice Sheepen also made two steps on the glowing charcoal. Hyperæmic patches occurred on his soles, which doubtless were the beginning of blisters."

Our Indian Contemporary—*Current Science*

To those who are interested in following from afar the remarkable increase in the appreciation of scientific education and research in India, which has recently become so apparent, our contemporary *Current Science* has been indispensable. This journal, which now enters upon its fourth year, is ably edited by Prof. C. R. Narayan Rao, of Bangalore, with the active co-operation of all the leading men of science in India. It has been their aim to provide India with a periodical similar in its aims to NATURE and in this they have undoubtedly been successful. In the July issue, the future of Indian university education is discussed at length, more especially as it affects the pass degree graduates who are so numerous in India. The problem of finding employment for these is not solely an Indian problem, but there it attains a magnitude not met with elsewhere. It is suggested that the courses of study require modification to meet this difficulty, but we doubt if this would provide more than a partial solution of the problem. We think that much might be done by the introduction of Civil Service examinations for the lower grades of civil servants, which would remove from the colleges many unsuitable students. The question is one well worthy of study by an independent committee.

THIS issue of *Current Science* contains also a number of valuable scientific articles. Of especial interest is that by S. Rangaswami and M. Sreenivasaya on the disease of sandal. The discovery, that this disease is insect borne, has resulted from research work in which the biochemists of the Indian Institute of Science, Bangalore, and the entomologists of the Forest Research Institute, Dehra Dun, have been prominent. This investigation provides an excellent example of the value of well-organised team work, and it should result in the control and the gradual elimination of this disease from the Madras and Mysore forests. We congratulate the editor and his collaborators on the high measure of success achieved by *Current Science* and we note with pleasure that in future the journal is to appear fortnightly instead of monthly.

Hittite Art

A REPRESENTATION of a bull in silver from recent excavations in Anatolia, and described as the most important work of art of Hittite origin yet discovered, is to be exhibited at the forthcoming Antique Dealers Fair to be held at Grosvenor House, London, W.1. The figure is seven inches high, and is mounted on bronze and inlaid with gold. It is dated tentatively at the third millennium B.C. As an evidence of high artistic culture, it is without parallel among Hittite antiquities. An obvious comparison with Sumerian bulls from Ur is suggested. To this, reference is made by Prof. Ernst Herzfeld, whose authority on Hittite objects is unquestionable. In an interview with a representative of *The Times*, which appears in the issue of September 16, he discusses the affinities of the Hittite bull with other finds from Anatolia and elsewhere, mentioning in particular the figurines from mounds in south Russia and the Caucasus, of which the best known are in the Hermitage Museum, and a terra-cotta bull (*Bos primigenius*) from Nihawand in his own collection, which belongs to the Early Bronze Age of the third millennium B.C. Prof. Herzfeld also directs attention to the principle, important in discussion of the qualities and characteristics of art in the ancient East, and of a relevance here, which will be immediately apparent to archæologists, that down to Achæmenid times verisimilitude in line is frequently sacrificed to an artistic convention in attitude, which assimilates one species to another. This is apparent in this example in the manner in which the legs of a bull are represented in an attitude essentially capriform. It is thus evident that even at the early date to which this bull is assigned, an art, Hittite in all essentials, already conformed to a generalised eastern convention.

Fen Drainage Problems

IN view of the contiguity of the fen district to the locality of the Norwich meeting of the British Association, the presentation at the meeting of a paper on problems in fen drainage was appropriate. Major R. G. Clark, the writer of the paper, pointed out that there is an estimated total of 1,279,000 acres of fenland and lowland in England and Wales protected by artificial works from inundation by the sea or flooding from the rivers conducting the surplus water to the sea, and that the Bedford Level, which extends into the counties of Cambridgeshire, Norfolk, Huntingdonshire, Isle of Ely and other counties, comprises about 836,000 acres of fenland. The Bedford Level is traversed by the Rivers Nene and Ouse which serve to subdivide it into the North, Middle and South Levels.

ARTIFICIAL works in this district date back to about 1631, when Cornelius Vermuyden, the celebrated Dutch engineer, was commissioned to convert the Level area into 'summer lands', which he did by constructing various barrier banks, new cuts, etc. He appears, however, to have allowed insufficiently for the shrinkage of the newly-protected land, mainly composed of peat, in illustration of which, a photograph was shown of a column at Whittlesea Mere, the top of which marks the original level of the ground when drained in 1851 and now stands 11 ft. above it. The paper described the means adopted to produce evacuation of the water, and instanced the modern pumping installation at St. Germans consisting of three oil-driven units of the Premier-Crossley horizontal *vis-à-vis* type, each of 1,000 b.h.p., coupled through reduction gears to a horizontal centrifugal pump constructed by Messrs. Gwynne's Pumps, Ltd., the capacity of each pump varying from 1,000 to 300 tons per minute according to tidal conditions. Mentioning that the Middle Level Board has spent more than half a million sterling on new works and maintenance during the past twelve years, Major Clark concluded with the affirmation that, in future, State assistance will become necessary, urging that it will be a national disaster if these large food-producing areas of fen and lowland are not maintained and protected.

Meare Lake Village, 1935

AN exceptionally interesting find in the excavations of the Somersetshire Archæological and Natural History Society at Meare Lake Village of the present season, which ended on September 19, is that of a timber substructure of a remarkable and unusual character in one of the mounds. It consists of a squared arrangement of oak beams, 11½ feet in length, crossed at the angles and secured by oak piles or corner posts placed vertically through the mortice holes. The arrangement was almost square, the area enclosed by the timbers being fifty-three square feet. The inner area was crossed by one large oak beam; and poles of alder and silver birch laid out in parallel order in both directions under the oak beams combined to form a raft-like structure. The earlier rectangular building on this structure would appear, judging from the position of piles around the area, to have been superseded by the more usual round dwelling, of which the superimposed hearths were found in the position and relation in which they were to be expected. A somewhat similar square timber structure was found in the west village some years ago, and traces of rectangular huts were found

at five points, though not *in situ*, in the Glastonbury Lake Village. From the range of finds in the area of excavation of the present season, it is evident that this quarter of the village was a centre for weaving. Weaving combs, bobbings, needles of bone and no less than twenty-four spindle whorls were found. Among other objects were an iron dagger with bronze fittings, bronze finger rings, yellow paste beads, three spurs of fighting cocks, linked bronze wire and two 'cheek-pieces' of horses' bridle bits. Among the finds from the excavations of this and previous seasons, to be exhibited in the new Wyndham Galleries of the Somerset County Museum at Taunton, is a mounted set of the spikelets and grains of *Triticum dicoccum* found at Meare, with a set of its modern counterpart by its side. These have been prepared by Sir Rowland Biffen.

Spanish Influence on Progress of Medicine

On the occasion of the International Congress of the History of Medicine, to be held at Madrid on September 23–29, the Wellcome Research Institution has issued a booklet illustrating Spain's contribution to medical science from the earliest times down to the discovery of cinchona in the seventeenth century. After alluding to Spanish contacts with former civilisations such as those of the Phœnicians, Carthaginians, Greeks, Romans and Visigoths, the work deals with the Hispano-Moresque Renaissance, which was remarkable for the foundation of schools of medicine and pharmacy and the establishment of hospitals, some of which were equipped with large libraries, as well as for the appearance of eminent medical men, including Albucasis, the author of a great medico-chirurgical treatise which remained the leading textbook until the time of William of Saliceto (1275), Avenzoar, the greatest of the Hispano-Moresque physicians, and Maimonides, the Hispano-Jewish philosopher and physician, the octocentenary of whose birth has recently been celebrated. During the sixteenth and seventeenth centuries a large number of hospitals were founded in different parts of Spain, especially at Barcelona, Granada, Malaga and Madrid. The outstanding medical personalities of the sixteenth century in Spain were Nicolás Monardes, of Seville, whose private museum of natural objects was one of the earliest, if not the first, in Spain; Francisco Hernandez, physician to Philip II and author of a monumental work on the natural history of Mexico; and Andres Laguna, physician to Charles V and Pope Julian III and professor at the University of Alcalá de Henares, where Cardinal Ximenes the founder had endowed six professorships of medicine and two of anatomy and surgery. The booklet is illustrated by facsimiles of pages from Spanish medical works, portraits of Spanish doctors and views of the old hospitals.

Snake Bite in the United States of America

In 1908, Prentiss Willson gathered reports of 740 bites by poisonous snakes covering a period of almost a century. That result gave an entirely false idea of the prevalence of snake-bite in the United States, for Dr. T. S. Githens now records 2,376 cases which have come to his notice during the past eight years, and estimates that there may be 1,500–2,000 cases each year (*Scientific Monthly*, August 1935, p. 163). It may be, also, that the number of snakes is increasing, for when wilderness is converted into farm land, small rodents increase greatly in number, and these form the mainstay of the snakes' diet. The danger to health varies most with the amount of venom injected, and this is closely related to the size of the snake involved, so that the most dangerous species are the large Florida and Texan diamond-backs. The only local measure having any real value is the application of a moderately tight tourniquet, associated with free incision of the site of the bite and the swollen area and persistent use of suction. But the mainstay of treatment is the use of adequate doses of antivenum, a specific serum effective against the bites of North American vipers, which has reduced the mortality rate from 14·3 to 3·7 per cent. Of the 72 persons who died in spite of serum treatment, 25 were near death when the serum was first given, and in 6 other cases death was due to gangrene resulting from too tight tourniquets; more than half were children less than fourteen years of age.

The Voyage of Peter Mundy

In the *Proceedings of the Linnean Society of London*, Session 1934–35, Part 2, Mr. N. B. Kinnear and Mr. F. C. Fraser direct attention to the remarkable journals and zoological notes from the voyage of Peter Mundy, 1855–56. Some very clever sketches are reproduced showing a remarkable vivacity, and his notes show that he was a careful observer. Three volumes of his travels have already been published by the Hakluyt Society; the fourth and final volume is being edited by Miss Anstey, who assisted the late Sir Richard Temple with the earlier volumes. The running bird from Ascension Island illustrated which "can neither fly nor swimme" is identified as a rail, now extinct, and the strange seal-like creature from St. Helena is thought to be a sea elephant, which, although never recorded from so far north, is a very strong swimmer, and it is apparently just possible that one could have reached this island. The third picture represents a whale, identified by Mr. Fraser as an adult Atlantic right whale. Mundy's description of the feeding mechanism is stated to be quite correct, and he is probably one of the first to have given a true account of this.

Zoological Gardens of Travancore

It is not easy to realise what great efforts are being made in all parts of the Empire for the interest and instruction of the people in matters of natural history. The Zoological Section of the Public Gardens at Trivandrum contained last year ("the year 1109 M.E.") 149 mammals, 225 birds, 26 reptiles and 20 fishes; and the growing popularity of the institution was indicated by an increase in the number of visitors to 462,566 from the 302,425 of the preceding year.

Extensive improvements were carried out, including the building of a new aviary, the extension of the carnivora house, and an open arena for lions and tigers. And "all the members of the menial staff of the three Sections were provided with suitable uniforms, for the first time, with suggestive badges for the respective groups; and the whole staff looks exceedingly smart when thus arrayed on ceremonial and festive occasions. . . . The year 1109 was one of the most progressive in the annals of the institution, and has marked an important land mark in the various stages of its development for years." (Administration Report to the Government of His Highness the Maha Raja of Travancore, 1109 M.E.)

Marine Biology in Ceylon

THE administrative report for 1934 of the marine biologist of Ceylon, Mr. A. H. Malpas, shows that as the results of restricted inspections by dredging of the pearl banks there were no spatfalls in the northern paars and Cheval paars. A certain number of second and third year oysters were, however, present, but not in sufficient quantities to offer a prospect of immediate fisheries, although if conditions are favourable they may provide heavy spatfalls. A scheme has been prepared for the establishment in Colombo of a fisheries research station combined with an aquarium which is under consideration. This provides in the first instance for a small biological research station capable of being enlarged as funds are available. It will be equipped with research laboratories and fresh-water and marine aquaria essential for fisheries investigation work. An aquarium will be attached, to which the public will be admitted. This is an alternative scheme to one outlined in earlier reports which provided for exhaustive investigations in these waters with a modern fishing vessel equipped with the latest fishing appliances in order to determine the lines on which the local industries could be most profitably developed, which the Executive Committee for Local Administration has definitely decided to abandon. Under the new scheme, the field of research will include investigations into life-histories and general bionomics of all aquatic animals of importance in Ceylon, into the culture of pearl and edible oysters, into the farming of estuaries and fresh-water fishes and turtle, and into the importance of various indigenous larvivorous fishes in relation to the suppression of tropical fevers and the breeding and distributing of the most active forms throughout Ceylon.

Baltic Countries

THE Baltic Institute, which was founded at Torun in Poland in 1926 for the investigation of Polish and Pomeranian economic problems, has widened its scope in the publication of a journal entitled *Baltic Countries*, which is to appear three times a year at the annual cost of five dollars. The August number contains more than a dozen articles, all in English, on various aspects—geographical, economic and historical—of Sweden, Finland, Denmark, Estonia and other Baltic lands. Russia and Germany are excluded from the scope of the review. The editorial committee of twelve is drawn from the universities of Baltic and Scandinavian countries, England and the United States. A supplement to the issue contains the first instalment of the proposed Baltic Year Book which gives the usual statistical tables. This is to be completed in four issues, and then published separately. *Baltic Countries* promises to be a useful addition to geographical and economic journals.

Religious Broadcasting at the Eucharistic Congress

THE broadcasting of the services at the International Eucharistic Congress of World Catholicism at Buenos Aires in October 1934 to the largest and most widely diffused religious congregation in history was made possible by the radio telephone. On the closing day, October 14, the Pope, Pius XI, speaking into a microphone on his desk at the Vatican, gave the concluding message not only to a million worshippers kneeling in the streets of the Argentine capital, but also, by means of retransmissions from Buenos Aires to broadcasting stations on three continents, to a very considerable proportion of the clergy and laity throughout the world. In *Electrical Communication* of July, two papers describe the broadcasting arrangements and the radio telephone system which rendered possible this world-wide service. No longer are the delegates to these international congresses crowded together in a cathedral with straining ears. Walls or park boundaries or national frontiers or even oceans now offer no restrictions. Without wireless, the management of the large crowds drawn from a metropolitan area having nearly three million inhabitants would have presented almost insuperable difficulties. Chile, Peru and Colombia were linked up by transcontinental land lines and Uruguay by a subfluvial cable. The able and willing co-operation of the Government telephone departments of many of the leading countries in the world ensured the success of the international broadcasts.

Industrial Power in Great Britain

AT the National Electrical Convention held at Bournemouth on June 3–8, a paper on industrial power supply was read by F. Forrest, H. Hobson and C. Taite. They examine very thoroughly the dependence of Great Britain upon her manufacturing industries and how much mechanical and electrical power they take. Although widely extended use is being made by industry of the public electric supply services, a still wider use is advocated, as it has a cumulative effect upon economy of production, and many of the existing mechanical power plants are not economical. The introduction of labour-saving devices has proceeded more slowly in Great Britain than elsewhere; mass production methods also are much more widely applied in the United States and Germany. Compared with her principal competitors, there is a relative deficiency in the total power equipment per wage earner of Britain. This deficiency is partly due to the nature of British industries, which demand a greater proportion of hand processes, and

in part to their earlier and more gradual development. The percentage of workers engaged in manufacture is appreciably higher in Britain than in the United States, France or Germany. The total horse-power has advanced from 1½ horse-power per wage earner in 1907 to 2·81 per operative in 1930. Taking the average price of coal and electric power to be 100 in 1922, their prices fell to 75 and 59 in 1932. The advent of the Grid has enabled great reductions in capital cost owing to the use of much larger dynamos. In 1934, the average size of *machine* ordered was 40,000 kilowatts, which is four times the average size of a generating *station* in 1926. Examples are given showing how the Grid is leading to the decentralisation of industry.

Progress of Welding

THE new Institute of Welding founded this year amalgamates the two organisations formerly known as the Institution of Welding Engineers and the British Advisory Welding Council. An abstract of the address of the new president, Sir Alexander Gibb, to the Institute appears in the *British Engineers' Export Journal* for July. It is pointed out that, on the Continent, there are many buildings more than twelve stories high constructed by welding. In Great Britain the entertainment hall at Bexhill is the first large building in which welding was used. Several all-welded ships have been constructed, and have proved very successful in everyday use. In most ships, including destroyers and cruisers, bulkheads and strength decks are welded. Welded underframes will be used for the Silver Jubilee train which will run from London to Newcastle (268 miles) in less than four hours—necessitating long stretches at more than 100 miles an hour. In the United States, the Burlington Zephyr diesel high-speed train, built of welded stainless steel, attains a speed of 100 miles an hour in its daily service between Kansas City and Lincoln, doing the 251 miles in four hours. In the electrical industry, practically all the largest machines are now fabricated by electric welding. In hydro-electric development, welded high-pressure pipe lines are the standard practice. Many bridges have been constructed in this way. In Belgium two dozen truss bridges are being built over the Albert Canal, some of the spans being 250 feet long. In Germany more than two hundred railway bridges have been built with spans up to 170 feet, and road bridges with spans of 300 feet.

Norman Lockyer Observatory

THE second edition of the Handbook of the Norman Lockyer Observatory (Sidmouth: Norman Lockyer Observatory. 6*d.*), compiled by Dr. W. J. S. Lockyer, director of the Observatory, is dedicated to the late Miss Winifred Lockyer who until her death in July 1934 voluntarily acted as assistant secretary and librarian. The handbook refers warmly to her willing and cheerful service, and to her many generous gifts. The beginnings of the Observatory date from 1912, shortly after the retirement of Sir Norman Lockyer from the Solar Physics Observatory at South Kensington, and the transference of that Observatory to Cambridge. To promote its development, the Observatory in 1916 was formed into a Corporation. The Observatory was originally known as 'The Hill Observatory', but in 1921 the Council of the Corporation changed its name to that which it now bears as a fitting reminder of its founder's eminence in astrophysics. The principal instruments are the 12-in. McClean telescope, the 10-in. Kensington telescope and the Mond photographic equatorial. The first two are devoted to astrophysical problems —the study of *B*-type stars which exhibit emission lines in their spectra, and the determination of spectroscopic parallaxes (of which more than 2,000 have been measured up to date) form the main investigations. The third instrument, presented to the Observatory by Sir Robert Mond four years ago, consists of a battery of four short-focus telescopes designed for photographing large regions of the sky. Of the history of the Observatory and its programme of work, the Handbook gives an interesting account, and it is well illustrated with photographs.

Mining Electrical Engineering

AT the annual conference of the Association of Mining Electrical Engineers held in Nottingham last July, suggestive comments were made on the directions in which engineering progress could be most helpful in mining. During recent years, notable advances have been made in developing safety lamps, flameproof switchgear of all kinds and signalling. In the latter department, experiments between the surface of the ground and the workings underneath have been made with a fair amount of success by means of wireless, but sub-surface radio still remains a possibility of the future. In his presidential address, Mr. A. W. Williams, whilst admitting the progress that has been made, urged that they must never be content with the present degree of efficiency. Engineers at the present time pay special attention to standardisation. Practically every commodity used in connexion with electrical apparatus is either standardised or is being studied with that end in view. He fears that this tendency will retard efforts to further research in the directions of safety and efficiency, and tends to put a check on individual initiative and investigation. Mr. Williams does not approve of some of the devices introduced to control apparatus at a distance, for they cannot always be trusted to work satisfactorily; they make for safety in some ways, but increase the risks in others. From the mining engineer's point of view, they offer few, if any, compensating advantages by increasing the efficiency of coal production.

Destructive Earthquakes in 1934

IN the last two numbers of the *Matériaux pour l'Étude des Calamités* (79–84, 152–155; 1935), M. Charles Bois has given a list of 54 destructive earthquakes that occurred during the year 1934. The only great earthquake of the series was that of northern Bihar on January 15. Three others, one in China and two in Mexico, may have reached the highest

of Prof. Milne's three degrees of intensity. The most remarkable feature of the year was, however, the occurrence of only one semi-destructive shock in each of such well-known seismic regions as Italy, Greece, Japan, the Philippines, California and New Zealand. The total number of lives lost was unusually small, in Bihar about 2,000, and in all the rest, according to M. Bois, the total is only 39.

Animal Welfare

THE third "Animal Year Book", published by the University of London Animal Welfare Society (price 2*s.* 6*d.*), contains a variety of articles of interest to naturalists. Most important of these are A. H. B. Kirkman's account of whales and whaling; a summing up of the state of affairs in regard to oil pollution of coastal waters by J. McMath and L. Parker; and a symposium in which correspondents in different lands abroad give summaries of their own country's legislative and other efforts for the protection of animals. The hon. editor is Dr. C. M. Knight.

Science in Hong-Kong and South China

THE first number of a new volume (4) of the *Hong-kong Naturalist* (May 1935) carries on the tradition of its predecessors in offering articles dealing with many different aspects of scientific knowledge. An excellent account of stone rings and their manufacture, and the first of a series of articles on the legends and stories of the New Territories are of archæological interest; and the curious Chinese habit of eating melon-seeds is described and discussed historically. The pipe-fishes and their relatives continue the synopsis of Chinese fishes, and the series on the birds and the orchids of Hong-Kong are continued.

Key to British Trees and Shrubs

A USEFUL key to British trees and shrubs has recently been compiled by C. T. Prime and R. J. Deacock (Cambridge: W. Heffer and Sons, Ltd., 1*s.*). The key is divided into two sections, the first giving the summer diagnostic features (chiefly the leaves), and the latter the winter features. The key is arranged in a simple flora style, and should not give rise to any difficulty. There are 57 diagrams. Unfortunately these are in very rough outline, and in many cases will not help in identification; this applies especially to the diagrams of winter twigs. More detail is not only desirable, but also essential, if these illustrations are to carry out their intended function. The price is high for a pamphlet of 39 pages.

Canadian Minerals

A USEFUL publication is "The Canadian Mineral Industry in 1934" published by the Department of Mines, Ottawa. It gives in alphabetical order, for a score of metals and some thirty minerals, details of occurrence, production and trade as regards Canada. Details are given also of important developments and prospective sources of further supply within the Dominion. The volume provides in a convenient form a complete survey of Canadian mineral resources and also authoritative figures.

Announcements

M. ALFRED LACROIX, perpetual secretary of the French Academy of Sciences and professor at the Museum of Natural History, Paris, has been nominated Grand Officer of the Legion of Honour.

THE tercentenary of the university of Budapest founded by Peter Pazmany in 1635 will be celebrated at Budapest on September 27–29, when the following, among others, will receive the title of doctor *honoris causa*: Sir Frederick Gowland Hopkins, Sir Charles Sherrington, Prof. Ludwig Aschoff, of Freiburg im Breisgau, Dr. G. Roussy, dean of the medical faculty in the University of Paris, and Prof. Anton von Eiselberg of Vienna.

THE following have recently been elected honorary members of the German Röntgen Society: Dr. Antoine Béclère of Paris, Prof. Rudolf Jaksch-Wartenhorst of Prague, Mr. A. Charles Thurston Holland of Liverpool, Dr. J. M. Woodburn Morison of London, and Dr. Pfahler of Philadelphia.

THE International Society of Medical Hydrology will hold its annual meeting in Brussels and Ostend on October 12–17, when the following subjects will be discussed: the action of carbon dioxide on the peripheral circulation, the therapeutic action of mud baths, and the therapeutic action of a sea climate. The first two subjects will be discussed in Brussels on October 13–14 and the third at Ostend. The intervening days will be spent on a visit to Mordorp and Spa. Further information can be obtained from the Secretary of the International Society of Medical Hydrology, 100 Kingsway, W.C.2.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A lecturer in agricultural botany in the Edinburgh and East of Scotland College of Agriculture—The Secretary (Sept. 25).

An entomologist in the Horticultural Research Station of the University of Cambridge—The Secretary, School of Agriculture, Cambridge (Sept. 25).

A part-time demonstrator in zoology in the University of Manchester—The Registrar (Sept. 26).

Junior assistant in the Directorate of Ballistics Research—The Chief Superintendent, Research Department, Royal Arsenal, S.E.1 (Oct. 3).

A research assistant in the Mathematics Department of the Imperial College of Science and Technology—The Secretary (Oct. 4).

A curator of the Department of Archæology and History, and a curator of the Departments of Ethnology and Ceramics in the Art Galleries of Glasgow—The Subscriber, City Chambers, Glasgow (Oct. 15).

A lecturer in structural engineering and mechanics in the Borough Polytechnic, Borough Road, London, S.E.1—The Principal.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 479.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Precursors of Coprosterol and the Bile Acids in the Animal Organism

THE transformation of cholesterol into coprosterol in its passage through the body involves a reduction of the $C_5 : C_6$ double bond, and a transition from the *allo*cholanic- to the cholanic-ring system. Although it is established that the bacterial flora of the intestine is concerned in the reduction process, the mechanism by which the stereochemical change is brought about is unknown. A clue was afforded by a study of the properties of cholestene-3 : 4-diol, a primary oxidation product which is formed under various conditions of mild oxidation from cholesterol, and is also a constituent of the resinous product called 'oxycholesterol'[1]. Being an α-glycol, this substance easily rearranges by loss of water into the corresponding ketone, that is, cholestenone. Since cholestenone (= coprostenone) yields coprostanone on reduction, which in turn is reducible to coprosterol (= coprostanol) and *epi*-coprosterol[2,3], we formed the working hypothesis that the reactive primary oxidation product, cholestene-diol, may play a role in cholesterol metabolism, giving rise to the formation of cholestenone as an intermediary product. On this assumption, cholestenone and coprostanone, and not cholesterol itself, are the immediate precursors of coprosterol which is formed from them in the intestine by bacterial reduction. Further, an explanation is afforded for the origin of the *epi*-hydroxycholane system in lithocholic acid (and the other bile acids ?)[4], which may be derived from *epi*-coprosterol by oxidative cleavage of the side chain with loss of acetone.

On subjecting this hypothesis to experimental test by means of feeding experiments on animals, we found that the addition of cholestenone to various diets poor in cholesterol gave rise to a large increase in the excretion of faecal coprosterol. This increase did not, however, account for the whole of the ingested cholestenone, and since only a small amount was excreted unchanged, it is possible that the remainder may have been converted into bile acids. This question, as well as the action of intestinal bacteria on cholestenone, is being further investigated.

It may be pointed out that a similar mechanism may underlie the metabolic processes leading from cholesterol to certain sexual hormones (progesterone, androsterone) which contain either a keto group or an epimerised hydroxyl at C_3.

Statistical Tests

IN a letter to NATURE of August 24, Prof. Karl Pearson states: "From my point of view, the tests are used to ascertain whether a reasonable *graduation* curve has been achieved, not to assert whether one or another hypothesis is true or false."

This assertion must come as a surprise to many who are familiar with Prof. Pearson's writings. It should not, however, be permitted to divert attention from the points raised in Mr. Buchanan-Wollaston's letter of August 3, for whatever may have been Prof. Pearson's original intention in introducing the term 'goodness of fit', and in publishing a table of the distribution of χ^2 (the theoretical form of which had been previously determined by Helmert in 1875), it is certain that the interest of statistical tests for scientific workers depends entirely from their use in rejecting hypotheses which are thereby judged to be incompatible with the observations.

It is certain, too, from many passages which could be cited from Prof. Pearson's own writings, that he has himself used the χ^2 test, not only in connexion with the graduation of frequency curves, but also as a means of testing the truth of theories or hypotheses. As one example, I may mention an appendix of five pages entitled "On the Test of Goodness of Fit of Observation to Theory in Mendelian Experiments" (*Biometrica*, **9**, pp. 309–314). In this paper he insists very clearly, and quite in accordance with modern usage, taking the extreme case $P = 0$, that either the theory or the observations must be rejected.

Mr. Buchanan-Wollaston's point that the χ^2 test, like the other tests of significance, is cogent for the rejection of hypotheses, but, in the opposite case, by no means cogent for their acceptance, deserves to be widely appreciated. For the logical fallacy of believing that a hypothesis has been proved to be true, merely because it is not contradicted by the available facts, has no more right to insinuate itself in statistical than in other kinds of scientific reasoning. Yet it does so only too frequently. Indeed, the "error of accepting an hypothesis when it is false" has been specially named by some writers "errors of the second kind". It would, therefore, add greatly to the clarity with which the tests of significance are regarded if it were generally understood that tests of significance, when used accurately, are capable of rejecting or invalidating hypotheses, in so far as these are contradicted by the data; but that they are never capable of establishing them as certainly true. In fact that "errors of the second kind" are committed only by those who misunderstand the nature and application of tests of significance.

South and East African Stone Age Typology

Two separate communications[1,2] this year on the archæology of South Africa bear indirectly on East African problems now being investigated in Uganda co this expedition.

n the first, Prof. Dreyer directs attention to the ne ilarity that exists, in his opinion, between certain of man skulls f und in association with implements th Early Mos el Bay type, and those of Kanjera, p nya. From the fact that these relics came from t base of a superficial black layer, he draws the c nclusion that they are of post-Pleistocene age. elow the black layer is a red sand deposit which ntains Late Stellenbosch implements (Acheulean m Levalloisian) with which, in a shelter, Prof. reyer has also had the good fortune to find human emains. He makes the dubious assumption that if e regard the Middle Stellenbosch as being the ulture of the same people "we at last come to the man] more or less contemporaneous with Leakey's Kanjera man".

The uncertainty of the association of the Kanjera fragments[3] with the Chellean tools found in the same rea precludes discussion of the relative ages of hese two sets of human remains; but as Prof. Dreyer uggests that owing to the thickness of the beds at Kanjera, Leakey may have over-estimated their age, t should be noted that the East African Chellean orms part of a very long evolutionary sequence and hat no late dating will satisfy the period of time equired. Moreover, Middle Stellenbosch is not the me stage as the Chellean found at Kanjera, but veral stages later. Actually, it is more akin to the ast African Early Acheulean. In Uganda this stage narks the beginning of a large-core technique for the manufacture of *coups de poing* and cleavers, and many of the finished implements have inclined platforms ery like the Clactonian, and simply due to the same ort of core technique for the detachment of flakes. Evidence is available in Uganda which suggests the resence here of a large flake culture, separate from, ut contemporary with, the Chellean.

In the second communication, Prof. van Riet Lowe again directs attention to the use of a prepared core technique for the production of large flakes, afterwards trimmed into handaxes and cleavers of Upper Stellenbosch age, and deals, let us hope, the final blow to the Victoria West Mystery.

In Uganda, geological proof of the date of the Early Acheulean is more or less settled, and shows that the industry had begun when the Intrapluvial in Pluvial II (Wayland) started, and is the same as the stage near the top of the red Bed III, at Oldoway, which similarly marks the climatic break. This oscillation may be equated with that between the Kamasian and Gamblian pluvials—the evidence being based on the succession of types following the Early Acheulean in Kenya, at Oldoway and in Uganda.

Owing to the fact that the Upper Stellenbosch is followed by Lower Fauresmith (Late Acheulean cum Old Levalloisian), whereas in East Africa the Early Acheulean is followed by several stages which are, at first, free from Levalloisian influence, one is inclined to think that the presence of a core and flake technique in a *coup de poing milieu* of early date is not necessarily evidence of the appearance of proto-Levalloisian, but rather due to the tardy borrowing of a Clacton or other early flake technique, which was especially suited to the production of cleavers.

In East Africa, as in South Africa, the earliest appearance of the true Levalloisian (with tortoise cores and faceted striking platforms) as a contemporary of a *coup de poing* group was in Upper Acheulean times.

Emission of Positrons from a Thorium-Active Deposit

USING the magnetic focusing method, we have investigated the energy distribution of the positrons emitted by a source of thorium-active deposit. The positrons were registered by counting the coincidences they produce in two Geiger-Müller counters[1]. The source from which the positron emission was observed was an aluminium strip 10 μ thick activated with thorium B + C. The total number of positrons was about 0·02–0·03 per cent of the number of β-particles from thorium C + C″.

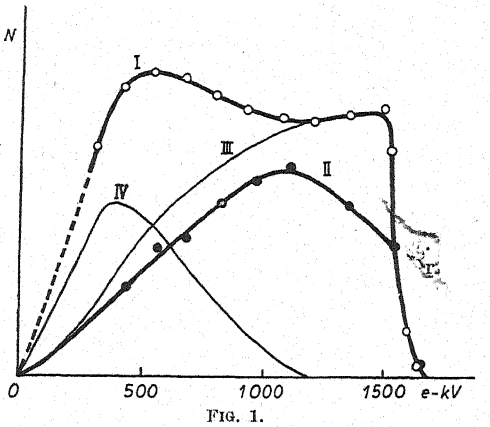

FIG. 1.

Chadwick, Blackett and Occhialini[2] inserted a weak preparation of thorium-active deposit in a cloud chamber, and observed a few (24) positron tracks issuing from the source. According to their data, the number of positrons was nearly 1 per cent of the number of β-particles, about 50 times the ratio we find in our experiments, but their statistical error was large. We have also compared the number of positrons emitted by the source with the number obtained by the process of materialisation of γ-rays from thorium C″. In this experiment the same source was surrounded by a lead shield 3 mm. thick; in this case the number of positrons measured was four to five times greater than with the source uncovered. In Fig. 1, curve I, the energy distribution curve of positrons emitted by the thorium-active deposit is given. For each point on this curve about 1,500 particles were counted, the statistical error being thus not greater than 3 per cent. The very abrupt fall of this curve near the end of the spectrum corresponding to the energy $h\nu - 2mc^2$ should be noticed. For comparison, we give a positron distribution curve, II, obtained by irradiating a lead strip 25 μ thick by the γ-rays from thorium C″. The asymmetry of this curve shows very clearly the effect of the nuclear field on the positive charge of the positron.

The very abrupt fall of the curve near the end of the spectrum ($h\nu - 2mc^2$) in the case of positrons from a thorium-active deposit is in good agreement with the theory of internal conversion of γ-rays on negative levels, worked out by Hulme and Jaeger[3]. In Fig. 1, curve III shows the theoretical curve for the conversion of the γ-line ($h\nu = 2{,}620$ ekv.) according to Hulme and Jaeger. The remaining portion (IV) of curve I, as we have already suggested in a similar connexion in the case of radium C, is probably to be ascribed to the effect of the β-radiation. If we separate in this way the effect of the γ-rays, we obtain for the probability of the internal conversion of the γ-rays of thorium C″ about $4{\cdot}5$–$5{\cdot}5 \times 10^{-4}$, close to the theoretical value of $4{\cdot}6 \times 10^{-4}$ given by Hulme and Jaeger. The remaining number of positrons, which we ascribe to the effect of β-radiation, amounts to about one positron per 1×10^4 disintegrating atoms of thorium C and C″. More accurate measurements with radium C showed that for the positron yield a value of 0·02–0·03 is to be accepted.

Formation of Drops in Supersaturated Vapour of Heavy Water

AN investigation of drop-formation in D_2O vapour, which was supersaturated by means of adiabatic expansion in a modified Wilson apparatus[1], gave the following values of the critical degree of expansion ($E = v_2/v_1$) for D_2O/H_2O mixtures, with and without an electric field:

Mol per cent D_2O	$T_{abs.}$	$E_{crit.}$ with electric field	$E_{crit.}$ without electric field
99	289·5	1·252 ± 0·003	1·230 ± 0·002
43	288·5	1·262 ± 0·003	1·240 ± 0·003
0	289·0	1·276	1·248

$T_{abs.}$ is the temperature of the vapour before expansion.

From the figures, the critical supersaturation of D_2O vapour at $T_{abs.} = 264$ was calculated to be 4·5, whereas the corresponding value of H_2O was 4·8. The result is quantitatively not in full agreement with Volmer's theory of formation of nuclei, which has been proved to hold good for a number of substances. According to Selwood and Frost[2] the surface tension of heavy water should be 5 dynes/cm. lower than that of normal water, and thus after Volmer the critical supersaturation of D_2O at $T_{abs.} = 264$ should be 4·2.

This slight discrepancy might be due to an error in the surface tension value of heavy water (too low), and this point is to be further investigated.

The large quantity of heavy water needed for the present investigation was provided by Norsk Hydro-Elektrisk Kvælstof A/S.

Isotopic Constitution of Gold from Band-Spectroscopic Examination

PROF. A. J. DEMPSTER has recently announced his mass-spectrographic result on the suspected go isotopes Au^{197} and Au^{199}, using his newly design positive ion source, and his results point to the no existence of Au^{199}.

For several years I have made many exposures the AuH violet $^1\Sigma \rightarrow {}^1\Sigma$ band system in the hope detecting Au^{199} by this method, using a 25-pla reflecting echelon, a quartz Lummer plate or a 4 plate transmission echelon. The resolving pow should be adequate to separate the two isotope lin if the ratio of Au^{199} to Au^{197} existed approximate in the ratio of 1 : 8·3 (or 1 : 7·0, if the atomic weig is recalculated on the $O^{16} = 16$ scale), as expect from the accepted chemical atomic weight of go namely, 197·21, and also if the two AuH molecu behaved normally, that is, had no apprecia electronic isotope effect compared with the alrea very small vibrational plus rotational effect (usua smaller than 0·05 $cm.^{-1}$). On none of the plates, which the main line is strongly over-exposed, has t satellite been recorded, in agreement with Dempste result.

Details of this work with photographs will published in the Institute's *Scientific Papers*.

Mechanism of Three-Carbon Tautomerism

WITH the object of throwing light on the mechan ism of three-carbon tautomerism, we have studie the equilibration of vinylacetic and crotonic acid in the presence of 1·05 mols of sodium hydroxide in dilute 'heavy water' at 100° C. As a check, we have also examined the behaviour of butyric acid under the same conditions. The isotopic ratio in both the recovered solvent and the water obtained by combustion of the residual sodium salts has been determined by a flotation method accurate to one part per million of density; the necessary purifica tions were carried out without loss of water, thus avoiding the possibility of isotopic fractionation.

The results are summarised in the following table in gm. of D_2O, calculated from the experimental density values and theoretical yields of solvent an combustion water respectively.

Acid	Original solvent	Final solvent		Combustion wate	
		Found	Calcd.	Found	Calcd
Butyric	0·6533	0·6542	0·6533	0·0001	0
Crotonic	0·8704	0·8658	0·8704	0·0002	0
Vinylacetic	0·8704	0·8613	0·8631	0·0068	0·00

It is evident that whilst there was no detectab interchange with butyric and crotonic acids, sub stantial interchange occurred in the case of viny acetic acid. The theoretical values in the latte case (corresponding to the interchange of one atom have been calculated on the assumption that n isotopic discrimination occurs in the interchang reaction. This assumption is not necessarily valid (cf. A. Farkas, "Orthohydrogen, Parahydrogen and Heavy Hydrogen", Cambridge University Press, 1935, p. 200) and it is proposed, in extending the

ork on interchange reactions of this type, to treat is aspect quantitatively.

Our results indicate, however, that there is a rallelism between isotopic interchange and isorisation. Of the various mechanisms which have en proposed for three-carbon tautomerism, those presenting the change as purely intramolecular ear to be unacceptable. Further discrimination tween intermolecular mechanisms must await aluation of the equilibrium constant of the exnge reaction; this work is actively in hand.

Fertilisation of Successive Broods of *Gammarus chevreuxi*

IN a letter in NATURE of May 18, p. 832, an account was given by Mr. K. W. Yarnold of some breeding experiments with red-eyed animals of a new stock (1933) of *Gammarus chevreuxi*, Sexton, crossed with the red-eyed Stock II (1922). Both these stocks originated in the Marine Biological Laboratory, and have always given red-eyed young when bred *inter se*, or when crossed with each other.

Mr. Yarnold, however, records an instance of a single black-eyed appearing in the offspring from a mating of two red-eyed (new red × Stock II red), the female of which had been previously mated with a black-eyed male. His explanation is "that some of the sperms from the previous mate of the female had remained behind and fertilised one or more of the eggs, causing the appearance of a heterozygous black-eyed specimen—not an unusual phenomenon in *Gammarus*".

It seems to me that if this explanation were orrect, the parentage of the offspring from any ross-mating would always be in doubt, and the enetical work done on *Gammarus chevreuxi* would ave no value. In my own experience—and I have orked on this species for twenty-three years—I have ever had a single instance of this carrying over of perm from one mating to the next in the many undreds of similar cross-matings made, and I think hat a study of the structure of the animals and of their mating habits proves conclusively that such an occurrence is impossible.

The female *Gammarus chevreuxi* has an external incubatory pouch made up of four pairs of brood-plates or lamellæ attached to the ventral surface of the 2nd, 3rd, 4th and 5th peræon-segments. The oviducts, one each side, open into the pouch on the ventral surface of the 5th segment. The pouch is held together when in use by long flexible hairs, and is open at both ends, where the lamellæ are separated by the width of the body. A constant steady stream of water is beaten through it from behind forwards by the pleopods, which serves to keep the eggs aerated and to remove all extraneous matter, for example, eggs which are not fertilised macerate, and are swept away by this current.

The cuticle, of hard unyielding chitin, is continuous over the entire body surface. This hard skin has to be sloughed off before the female can mate, and mating can only take place directly after the moult while the new skin is soft and elastic enough to permit of the passage of the eggs through the oviduct apertures into the pouch.

In moulting, the cuticle cracks across the *dorsum* just behind and around the head, and the animal heaves itself up and draws out backwards, leaving the old skin unbroken on the ventral surface. The moults are always perfect to the last detail in healthy specimens but, unless carefully watched for, they are very rarely seen in this condition owing to the habit amphipods have of devouring their cast skins immediately after ecdysis.

Sickly animals have great difficulty in moulting, and an incomplete or imperfect moult always ends in death, but sickly animals do not breed. I have never seen a healthy *Gammarus* pair with an unhealthy one; it may take hold of it, but only for the purpose of killing and eating it, never for breeding.

Fertilisation takes place outside the body. The male, which has paired with and carried the female for some days, assists her in moulting, and then it ejects the sperm into the open pouch. The female commences to extrude the eggs, and as she does so, she breaks free and resists any further mating. No pairing, even, takes place until she is once more in the right physiological condition, and no mating again without a complete moult.

We have made it a rule here, in all cross-matings, after the females moult, to give the pair a fresh bowl, water and food, so as to avoid any confusion with the offspring of a previous mating. The young are semi-transparent and only a millimetre in length on hatching, and as their instinct is to keep out of the light, it is sometimes very difficult to find them among the debris in the bowl.

Taking these facts into consideration: (*a*) that the animals never pair until the female is in the right physiological condition, and that the female will resist being taken unless in this condition; (*b*) that, once paired, they remain together until mating is over; (*c*) that mating must always be preceded by a moult; (*d*) that the animal in moulting comes out of the old skin, on the dorsal surface, leaving the ventral surface unbroken; (*e*) that the old pouch is sloughed off as a whole (with any young that may still be in it); (*f*) that fertilisation takes place in the open pouch; (*g*) that the sperm of the new mating is ejected into the new pouch; and (*h*) that a steady current of water is driven through the pouch from end to end during the whole period of incubation, I think it is evident that some other explanation than the one given by Mr. Yarnold for the appearance of a black-eyed young in his red-eyed cultures must be looked for.

Distribution of Nematodes in the Small Intestine of the Sheep

IN the course of ecological studies on the nematodes of the small intestine of sheep, particularly during their parasitic existence, it has become apparent that the manner of their distribution throws light upon the relation between host and parasite.

The jejenum is the favoured region of infection of species naturally occurring in sheep; those of any one genus share a common area, while species of different genera vary in the degree to which their infections overlap.

In healthy sheep the species: *Cooperia curticei*, *Nematodirus filicollis*, *N. spathiger*, *Strongyloides papillosus*, *Trichostrongylus colubriformis*, *T. vitrinus*, have each a normal frequency distribution which retains its identity throughout the period of infection; probably other species normally parasitic in sheep have a similar form of distribution. The position of the peak numbers of each species may vary in different animals, but its relation to those of other species in mixed infections is constant. For example, the peak of infection of *N. filicollis* always occurs at a shorter distance from the abomasum than that of *N. spathiger*, while those of species of different genera tend to array themselves along the intestine in the following order: (1) *Trichostrongylus*, (2) *Strongyloides*, (3) *Nematodirus*, (4) *Cooperia*. With increase of the distance of peak numbers from the abomasum there is a correlated increase in the area of distribution of the greater numbers of a species. Generic differences in this connexion are marked.

From the constancy of the form of distribution in sheep of various ages, under various conditions, at different times of the day and at different seasons, it is concluded that:

(1) Neither active nor passive migration on the part of adult worms takes place.

(2) The site of infection is determined during the larval stage.

(3) The stimuli causing larvæ to take up their station are present in the contents of the small intestine, and arise in the duodenum at the point of entrance of the bile and pancreatic juice.

(4) Specific differences in distribution are due to inherent dissimilarities in rates of reaction to the stimuli.

(5) *Trichostrongylus* spp. respond to stimuli in the abomasum as well as in the jejenum. *T. axei* is sensitive to these, but *T. colubriformis* and *T. vitrinus* are less so, with the result that the populations of the latter two species become divided between the abomasum and the small intestine. Other species found in the small intestine in their passage through the abomasum apparently do not remain there long enough to enable stimuli to have effect upon them.

There is evidence that in unhealthy animals distribution is erratic.

C. oncophora, *C. punctata* and an unidentified third species of *Cooperis* are normally parasitic in cattle. In sheep they have an erratic distribution, and this, I believe, is an expression of their inadaptability to this host.

Fibre Forms in Animal Hairs

UNDER the above title Mr. H. J. Woods[1] proposes three alternatives to the 'weathering' hypothesis tentatively advanced by me[2] to account for supernormal curvature in the apical region of certain guard hairs. Of the opposing evidence, it will suffice to point out that, in the light of a previous communication by Woods[3], the fibres should, if his views are correct, easily acquire permanent set. If the phenomenon is due to extensive oxidative degeneration, this should be impossible. Straightening the fibres and steaming under various strains for periods up to one hour, then releasing and re-steaming resulted only in further contraction. Moreover, differential super-contraction does not follow strain in saturated sodium bicarbonate solution, which has a considerably higher *p*H than the maximum record for suint.

However, Woods's suggestion that asymmetry of lateral bonding may exist is very interesting—at least, as a contributory factor—although there is record of super-contraction being produced chemically sound α-keratin by the action of stea alone. Structural asymmetry of some kind is pro ably a widespread phenomenon, occurring in sou as well as in damaged fibres. Experimental eviden in support of this view will appear in due course.

Flying Fishes

DURING a voyage down the west coast of Afric I have been watching the flying fishes, moved par by vague recollections of the contradictory opini that have been published regarding their flig Without the literature I cannot make specific ference to the controversies, but a brief summary what seem to me the most obvious facts about 'flight' of flying fishes may be of interest.

(1) The motive power is the same in the air a the sea: it is that of the tail-shaft musculat exerted through the tail against the water.

(2) The flight is usually started by a swi at a low angle up to and through the surface this fails, for example, through jostling in the fish is easily able to make a 'standing star the surface itself; a quivering vibration of the tail launches it almost instantaneously into full flight.

(3) The same manœuvre is regularly used to prolong the flight. At the end of the initial skim the fish often abruptly dives, but almost as often it dips the lower blade of the tail into the water instead and drives itself on for another stage. This may be repeated up to five or six times. It is perhaps the easiest thing to observe about the actions of a flying fish, and it is a never-failing surprise to see how short is the duration of the quivering dip and what a vigorous fresh impulse is derived from it.

(4) There is never the slightest sign of any impulse being derived from any other source. The fins during the flight are stiffly spread; they are used with great skill as planes, but never as wings.

(5) The flight is not a blind rush; while its way lasts, the fish can steer and turn up and down the waves and along them as gracefully as a petrel.

(6) The usual end of a flight is a sudden dive with shut 'wings'. But sometimes the dive is preceded by a sailing action with slightly up-tilted body and planes, like a seagull gliding to rest on the sea—one of the prettiest things a flying fish does.

(7) The flight is made at all angles to the wind, and in any wind from a calm to half a gale. Naturally the most difficult direction is down-wind, because the fish must push off at a considerably greater speed than that of the wind in order to rise at all. For the same reason a down-wind flight is made in a noticeably tilted-up position; it is in the nature of a prolonged sailing to rest.

(8) It is probably true that the fishes fly more freely in sunshine than in dull weather, but they do fly under an overcast sky as successfully as in sunshine. They are also known to fly at night, especially when they are disturbed by artificial light.

A good deal of unnecessary mystery seems to have been made about the flying fish's flight. The real mystery is the acquisition, by this one small group, of a fin and tail structure adapted to 'flight' and a singular adroitness in using it.

Structure of the Proboscis in Blood-sucking Diptera

WITH reference to Dr. B. Jobling's letter[1], I wish to point out that, as already mentioned[2], the hypothesis advanced by me concerning the feeding mechanism in blood-sucking diptera was of a tentative character, and that the object of my communication was not to generalise, but to report certain observations made by me on the feeding mechanism in one species of blood-sucking fly, namely, *Stomoxys calcitrans*. As a matter of fact, I have since carried out a large number of dissections upon specimens of several species of *Culicines* after feeding them on a strong solution of eosin sweetened with sugar, and while in a few instances no staining was found to have occurred in any part of the proboscis, in others it was the labrum-epipharynx that was found to have taken the stain along the whole of its length, indicating that the food-channel in insects of this class is probably formed by the apposition of the labrum-epipharynx and the hypopharynx.

As to the salivary duct in *S. calcitrans*, it terminates, as already mentioned, at the base of the hypopharynx, the lumen of the latter being a groove running centrally to near its tip.

Points from Foregoing Letters

FEEDING experiments on animals, carried out by Dr. O. Rosenheim and T. A. Webster, have shown that the immediate precursor of faecal coprosterol is not cholesterol but cholestenone, arising presumably from a primary oxidation product, cholestene-diol. The possible role of cholestenone in the conversion by the animal body of cholesterol into bile acids and certain sexual hormones is discussed.

The interest of statistical tests for scientific workers, Prof. R. A. Fisher writes, lies in their use in rejecting certain hypotheses incompatible with observations. He agrees with Mr. Buchanan-Wollaston that the logical fallacy of believing a hypothesis to be true merely because it is not contradicted by the available facts, does frequently occur.

The type and succession of prehistoric stone implements (Chellean, Acheulean) found in East Africa (Uganda) are compared by T. P. O'Brien with those from South Africa, recently described by Prof. Dreyer and by Prof. van Riet Lowe, and their bearing on the geological age of Dr. L. S. B. Leakey's Kanjera man is critically discussed.

The number and energy distribution of positive electrons emitted by thorium-active deposit agrees with the view that the electrons are produced by the materialisation of γ-rays of thorium C″, according to measurements by Prof. A. I. Alichanow, A. I. Alichanian and M. S. Kosodaew. The graphs show a residual effect ascribed by the authors to the production of positrons accompanying negative electrons (β-radiation).

The critical supersaturation at which drops of heavy water are formed (by adiabatic expansion) has been determined by Dr. L. Tronstad and H. Flood. They point out that if the value obtained is to agree with Volmer's theory of the formation of nuclei, the surface tension of heavy water must be greater than that reported by Selwood and Frost. (H. Lachs and J. Minkow have actually reported, in NATURE of August 3, p. 186, a higher surface tension for heavy water.)

Spectrographic investigations by Dr. Sunao Imanishi of the violet bands of gold hydride indicate the absence of a gold isotope of mass 199; his findings are in agreement with the negative result obtained by Dempster with the mass-spectrograph.

Drs. D. J. G. Ives and H. N. Rydon, from the results of equilibration experiments in dilute 'heavy water', deduce that purely intramolecular mechanisms for three-carbon tautomerism are not acceptable.

To account for a black-eyed offspring of the freshwater shrimp *Gammarus chevreuxi* of two red-eyed parents, K. W. Yarnold assumed that some sperms from a previous black-eyed mate had remained behind and fertilised the new eggs. As such an occurrence would render doubtful all genetical work done with that species, Mrs. E. W. Sexton gives a full account of the mating habits of *Gammarus*, indicating that no such successive fertilisation can occur.

The location of various species of parasitic nematodes in the small intestine of the sheep has been investigated by J. H. Tetley. It is concluded that the site of infection is determined during the larval stage, and that the stimuli determining the position arise in the duodenum at the point of entrance of the bile and pancreatic juice.

Dr. R. O. Hall finds that straightening and steaming certain animal (guard) hairs with supernormal curvature at the tip results in further contraction. This evidence, he maintains, opposes the three alternatives put forward by H. J. Wood to the 'weathering' hypothesis suggested to account for the apical curvature of those hairs.

Observations on the flying fishes off the West African coast are reported by Dr. E. L. Gill. The fishes fly through the air by repeatedly dipping the lower blade of the tail in the water in order to propel themselves, using the fins as planes.

Divine Kings in Southern Nigeria

AMONG the Umundri group of the Igbo of southern Nigeria, there are two divine kings who are the spiritual heads of the people, and occupy different towns in the Akwa District, Onitsha Province. Originally there was only one king, but dissensions arose and part of the town of Aguku seceded to found Oreri with its own divine king. The descendants of the royal family live at Aguku and claim descent from a sky-being, Eri, who was sent down by Chiuku, the sun-god. They call themselves Umundri and declare that they are not Igbo. The king is chosen from three, originally four, royal families and is usually a youngest son, whose choice must be accompanied by wonders and signs. The coronation ceremonies, which have been studied by Mr. M. W. D. Jeffreys, administrative officer (*Africa*, 8, 3), have the twofold object of transforming a man into a god and of recreating the world. One condition must obtain invariably. Both the candidate's parents must be dead. Also he must make three prophecies which must be fulfilled. The ceremony opens with ritual death, burial and resurrection. The candidate remains buried for several hours and his tree of life is cut down and the usual sacrifices made. When the body is exhumed at sunset a banana-stem takes its place. The candidate's body is whitewashed with clay and water that he may fulfil the prayer that he shall rise with a vivid and shining body. He discards his ordinary clothes and thereafter wears only white or blue Igala ones. Copper greaves are put on his legs, but he goes barefoot. Henceforth he is a god, and his person sacred. His first wife, or queen, is also whitened and wears white garments. Together they begin a circumambulation, which occupies several months. On his return to Aguku, the king may never leave the royal city again. At the close of a year, before he ascends the throne, a ritual combat takes place in which he overcomes first a young and then an old man.

Amber in Palæolithic Times

AMBER, which becomes abundant in neolithic times, is rare on palæolithic sites. The first specimen of palæolithic age was found at Arensan (Pyrenées) and some fragments appeared at Isturitz, where also the Comte R. de Saint-Périer found a bead, the first find of a definite form. Some fragments have also been recorded on central European sites. The Comte de Saint-Périer now reports (*L'Anthropologie*, 45, 3–4) the discovery in October 1934 of the first specimen of palæolithic sculpture in amber. It was found in the Isturitz cave in the middle of a stratum, of which the age had already been determined as lower Magdalenian. It was beneath another Magdalenian level, which itself was beneath a stalagmite sheet. There can be no question, therefore, of an intrusion. The character of the material was not at first recognised. It was thought to be ivory; and it was only some time after that it was suggested by the Abbé Breuil, when he saw the object in the laboratory, that it might be amber. This opinion was confirmed by tests applied in the laboratory of the Louvre. The sculpture represents the head of a horse, of which the anterior portion has suffered an ancient fracture. The head is massive in form, with a heavy mane; the neck, where it joins the head, is thick. The eyes, which are level with the surface of the head, are differently treated on either side. The musculature is well marked, especially on one side. The style is good and typically Magdalenian. The patination on one side is reddish-brown, and on the other yellowish-orange. Before this find, objects of art carved in amber were not known before the mesolithic, when animal figures appeared in Prussia and Scandinavia. Objects of neolithic age which have been found do not include animal figures.

An Ancient Aztec Herbal

THE Smithsonian Institution has published a pamphlet to make known the discovery of the Badianus Manuscript in the Vatican Library ("Concerning the Badianus Manuscript, an Aztec Herbal, 'Codex Barberini, Latin 241' (Vatican Library)", by Emily Walcott Emmart. Smithsonian Miscellaneous Collections, vol. 94, No. 2). This treatise—a herbal describing the various plants and other materials used in Aztec medical prescriptions—was the work of two Aztecs who were educated at the College of Santa Cruz, founded by the Spaniards in 1535. Composed originally in Aztec, it was immediately translated into Latin in 1552. The chief author appears to have been a certain Martin de la Cruz, the other was Juannes Badianus, the translator. The first chapter deals with head ailments; the second describes the treatment of sore and bloodshot eyes, cataract, fever and insomnia; the third is devoted to ear infections. Two interesting plants are described as cures for pain, which can be identified as being members of the *Datura* family. Besides the plants, various animal products, stones, earths and carbon, salts, 'bezoar stones', and others, were used in various concoctions. Facsimiles are given of the first and last pages of the Badianus Manuscript, and of the plate of the two plants of the *Datura* family. It is proposed to publish a facsimile of the full manuscript with its 91 colour plates should funds become available.

Alligator-Lizards in South-West America

A SYSTEMATIC study of the natural history of *Gerrhonotus* in south-western America (H. S. Fitch, *Trans. Acad. St. Louis*, 29; 1935) describes the alligator-lizards as showing indications of learning and rapid habit-forming, ranking high among reptiles for intelligence. These wood inhabitants exist on a diet ranging from the larger insects to small mammals and birds' eggs; hibernation and viviparity vary with the climatic characteristics of the habitat. As a means of self-protection, they will encircle a tree-branch with their bodies, holding the tail firmly in their mouths, or discard their tails as a decoy to divert the attention of the snakes and hawks that prey upon them. The high percentage of regenerated tails suggests that this ruse is frequently successful. The alligator-lizards show practically no trace of social behaviour; mating occurs once annually at a definite season governed by locality and species.

Gill Formation in the Embryo of *Triturus*

IN the earlier stages of the embryo of *Triturus*, gill formation can be effected by transplantation of any portion of the body surface, excepting the medullary plate; for self-differentiation of the surface tissue in this way, mesoderm appears to be essential for the formation of the gills (M. Ichikawa, *Mem. Coll. Sci., Kyoto Imp. Univ.*, Ser. B, 9; 1933). Transplantation of all three germ layers invariably causes perfect gills to develop, while if the endoderm is excluded in such grafting, gills are sometimes produced and sometimes not. As the embryo develops, the gill-forming faculty becomes increasingly restricted to the forward portions of the body; when the tail-bud appears, only the branchial ectoderm is capable of producing perfect gills, which have in all cases a definite polarity. The power of gill-production is now located solely in the proper position—the differentiated branchial ectoderm.

Colour Changes in the Eye of a Grasshopper

IN 1916, Prof. Okazaki noticed that the eyes of a long-horned grasshopper (*Hexacentrus japonicus*) were jet black when he collected the insects one evening, but on the following day were golden yellow. Several other insects show a similar change, and Hajime Uchida has studied the changes in another long-horned grasshopper, *Homorocoryphus lineosus* (*J. Fac. Sci., Imp. Univ. Tokyo, Zoo.*, 3, 517; 1934). Surrounding the cone of each ommatidium are two principal pigment cells which change their position according to the intensity of the light. They contain black granules. Accessory pigment cells occupy the interspaces between ommatidia, and contain yellowish reflecting pigment granules. When the eye is exposed to light, the principal pigment cells and the granules within them retreat proximally, so that the apparent colour is due to the accessory cells. In the dark-adapted eye the principal cells entirely encircle the cone, pushing aside the accessory cells. When light-adapted insects are transferred to a dark room, the distal migration of pigment granules takes place very rapidly during the first twenty minutes, and thereafter slows down, so that the full dark-adapted condition is attained only after fifty minutes. In the reverse process, the rate of retreat of the black pigment granules in the principal pigment cells is proportional to the intensity of the light.

High Temperature Variations in Fungi

DR. B. BARNES has shown that heating the spores of *Eurotium herbariorum* and *Botrytis cinerea* has induced relatively permanent variations in the morphology of these two species. He has now studied a third fungus, with similar results ("On Variation in *Thamnidium elegans*, Link, induced by the Action of High Temperatures", *Trans. Brit. Mycol. Soc.*, 19, Part 4, June 1935). Two separate variants were produced when spores were heated to 55° C. for two minutes, and another mutant appeared on heating to 70° C. for a similar period. Temperatures above 70° C. killed the spores. *Thamnidium elegans* is normally a fungus of stable character, and remains unaltered through several years of artificial culture. The variants produced by the lower temperature began to revert to the original form after three years of culture; but the other has remained permanent. Variations relate to the size of the spore-bearing head and prolificacy of spore production.

Secondary Spores of Polyporous Fungi

A SHORT paper by S. R. Bose in *Phytopathology* (25, No. 4, 426–429, April 1935) traces the cytology of secondary spore formation in *Ganoderma*. Peculiar bodies which are really hyphal projections appear in the hymenium, between the normal basidia. The projections are at first binucleate, but the two nuclei quickly fuse, then split into a number of dark-staining bodies, which migrate to the apex of the protrusion. This swells to form the secondary spore, and the dark bodies afterwards reunite to form the spore nucleus. The paper mentions other Polyporaceous fungi which produce secondary spores, and discusses the effect of weather upon their appearance.

Identification of Australian Woods

NOTEWORTHY contributions to this important, but difficult, problem are contained in two publications (Technical Papers Nos. 15 and 16; 1935) issued by the Council for Scientific and Industrial Research of Australia. The first, by W. E. Cohen, deals with the coloured species of *Eucalyptus*, and describes a series of simple chemical tests such as the determination of the alkalinity of the ash, extraction tests, colour- and turbidity-reactions between extracts of the wood in various solvents and ferric chloride, water, or potassium ferricyanide, and several specific chemical reactions of a similar nature. These tests have been combined to produce a systematic scheme of identification into which fall the 540 samples examined; these represent 37 species. The second paper, by H. E. Dadswell and A. M. Eckersley, is concerned with the remaining principal commercial Australian timbers, which are mainly pored woods (hardwoods). The scheme of identification evolved in this case is based principally on those macroscopic features which can be conveniently ascertained by means of a hand-lens, such as the nature of the pores, parenchyma, rays, gum ducts and ripple marks. These are supplemented in some cases by microscopical data, and in a few instances by chemical tests.

Geology of Northern Nevada

WE have received from the United States Geological Survey, Bulletin 847—A, The Contact Mining District (Elko County, Northern Nevada) by F. C. Schrader. The district appears to consist of carboniferous rocks, mainly carboniferous limestone, intruded by a mass of grano-diorite with intrusive dykes of alaskite, andesite and other igneous rocks, the Palæozoic rocks being in places locally covered by Tertiary rocks, partly volcanic and partly stratified deposits. The ore deposits appear to be mainly distributed round the border of the grano-diorite, but are also associated with alaskite dykes. A large number of mines have been worked in this district, originally apparently for gold, but more recently for copper, which appears to be the main product, though none of the workings is very deep. Of course, with the low price of copper in recent years, operations have fallen off considerably.

Rock Salt in Road Construction

SECONDARY roads serving as connexions and feeders to the main highways are of two types, the 'floating surface' type and the soil stabilised type. The former is made by adding loose gravel or similar material to the road bed, the latter contains gravel

kept in place by a material containing clay which acts as a binder. The floating surface type requires almost constant maintenance as the loose material is cast about by the traffic. Unfortunately, clay expands and contracts between fairly wide limits when alternately damped and dried by rain, wind and sunshine. Untreated clay shrinks as it dries, and permits embedded material to form a floating surface. In *Roads and Streets* (U.S.A.) of August, the results of experiments on the effect of salt on clay, by Prof. H. Ries of Cornell University, are described. He finds that clay treated with salt shrinks much less than untreated clay and that it holds moisture much better. The rate of the capillary action of the soil moisture is slightly increased and this leads to the compaction of the soil producing greater density. Actual road construction in America during the last three years has proved the effectiveness in practice of rock salt for road stabilisation. It is not necessary to add salt to more than the top three inches of the road. The quantity of salt recommended varies from 8 tons per mile for a road 14 ft. wide to 12 tons per mile for a road 20 ft. wide. The amount of water required to produce the best compaction is more than sufficient to dissolve all of the salt. In dry weather a properly moistened surface 'sets up' in less than a day and requires little attention.

Research on Motor Vehicles

THE Research and Standardisation Committee of the Institution of Automobile Engineers has recently issued its fourth annual report. Two reports have been issued of the researches on cylinder wear, special attention being paid to the influence of various constituents in the lubricants used on the wear by abrasion and corrosion. The engine was run on medicinal paraffin to which various fatty acids were added. Much useful information was obtained in this way. A report of experiments on the wear and friction of brake linings has been issued, and gives the results of experiments on twenty-two different materials. The rate of wear and the coefficient of friction was found over a temperature range of 100°–400° C. Many manufacturers are urging the importance of carrying out further experiments on 'brake squeak', as definite information concerning its origin is lacking. It is interesting to notice that the results of the tests are improving the durability and performance of the vehicles. The vehicle operators therefore get the main benefit from these researches.

Ignition of Firedamp by Compression

WE have received from the Safety in Mines Research Board, Paper No. 93; not only is this paper interesting in itself, but it derives further interest from the fact that it is one of the last pieces of work done by the late Prof. H. B. Dixon (Mines Department: Safety in Mines Research Board. Paper No. 93: The Ignition of Firedamp by Compression. By the late H. B. Dixon and J. Harwood. Pp. 23. London: H.M. Stationery Office. 6*d.* net). The paper describes a series of laboratory tests, carried out with an appliance designed for the purpose, of the ignition temperatures and ignition pressures of various combustible gases together with air, mixtures of methane and air being, of course, the most important for the purpose of the Safety in Mines Research Board. It was found that a wide range of mixtures between 2 and 75 per cent of methane could be ignited, but that mixtures containing between 7 and 7·5 per cent of methane had the lowest ignition temperatures when compressed, the pressure being about 20 atmospheres and the temperature being about 450° C., whilst mixtures of firedamp and air containing less than 5 per cent or more than 14 per cent of methane cannot be ignited in the ordinary way. It was further found that in order to ignite mixtures of methane and air, containing 7–10 per cent of methane with air at ordinary pressures, this mixture could easily be ignited when the hole in the end of the pressure piece of the apparatus was about 2·25 mm. in diameter; when larger holes than these were used, copper discs of varying thickness, through which a hole was blown by the operation itself, were found capable of igniting the methane-air mixtures. It is obvious that these experiments can, as indicated by a paper of Dr. Wheeler's, have certain results in practice, but the paper itself does not indicate the practical application of the results obtained experimentally.

Mandelic Acid in Urinary Infections

THE use of the so-called 'ketogenic' diet in the treatment of certain urinary infections is now well established. Mandelic acid has recently been shown to serve as a useful substitute. The acid has now been put on the market (NATURE, Sept. 7, p. 401). As supplied by the British Drug Houses, Ltd., London, N.1, the daily dose recommended is 12 gm. The acid is issued in the form of 3 gm. tablets, each containing also 1·6 gm. sodium bicarbonate, to neutralise the acid, and flavoured. One tablet should be taken after each meal dissolved in two tablespoonfuls (one fluid ounce) of water. As the acid exerts its bacteriostatic effect only in an acid urine, it is also necessary to give a drug which will keep the acidity of the urine at or below *p*H 5·3. For this purpose, ammonium chloride is recommended, and two 1 gm. capsules should be taken four times a day after the mandelic acid. The *p*H of the urine is conveniently tested with methyl red, a slightly pink colour indicating a *p*H of 5·3 or slightly less. The British Drug Houses, Ltd., issues a special outfit for the treatment, including mandelic acid tablets, ammonium chloride capsules and the indicator.

Photometry of Nebulæ

THE first of a series of studies of extra-galactic nebulæ by P. C. Keenan (*Astrophys. J.*, 82, 62) describes the method in use at the Yerkes Observatory for measuring the total magnitudes of nebulæ by comparisons of extra-focal images. This work forms part of a co-operative survey of nebulæ organised by the International Astronomical Union under the leadership of Dr. Hubble, of the Mount Wilson Observatory. The zone assigned to the Yerkes Observatory being from + 50° to the North Pole renders it possible to make direct comparisons with stars of the North Polar Sequence. Nebular images only slightly out of focus are used (the total blackening of the plate being measured), and the most serious source of error is the irregularity in the shapes of the images. Corrections are applied for differential atmospheric extinction and for size of image, the probable errors of the resulting magnitudes being about ± 0·06. During the progress of this work, a number of hitherto uncatalogued nebulæ were discovered. A list of thirty-two of these, with their positions and magnitudes, is given at the end of the paper.

Hearing and Aids to Hearing

DURING the discussion on "Hearing and Hearing Aids" held by Sections J (Psychology) and I (Physiology) of the British Association in Norwich on September 5, the major point considered was the effect of intense stimuli upon the performance of normal and deaf ears. The matter was approached from two points of view; of the increase of intelligibility of speech, when amplified, for partially deaf patients, and of the effect of listening to loud pure tones upon the acuity of pure tone hearing in both normal and partially deaf ears.

Dr. A. W. G. Ewing and Mr. T. S. Littler, of the Department of Education of the Deaf, University of Manchester, first described the apparatus which they are using for investigating the first of these points. This consists of a microphone and amplifier situated in a small sound-proofed room. The output of the amplifier passes via a decibel attenuator to the reproducing system. In this way, the intensity of the sound applied to the observer's ear by speaking into the microphone can be varied at will from a subnormal loudness to one of 110 decibels above the normal threshold. The power-level reached at any moment can be read from an output meter connected in the outgoing power-line.

Dr. Ewing then dealt with the effect of amplifying speech by these means upon its intelligibility for partially deaf observers. He showed, for example, that out of eight such observers, for five the intelligibility could reach 100 per cent. Of these five, two required an intensity level of 110 decibels, and the remainder required 70–90 decibels. In a control experiment upon normal subjects, 100 per cent intelligibility could not be achieved with loudnesses greater than 70 decibels; the intelligibility tests employed were of normal speech one foot from the microphone, and of 20 consonant sounds specially chosen.

Whilst it is clear that the number of observers used is too small to permit of any generalisation with regard to the deaf population as a whole, it is none the less a remarkable fact that more than half of these cases were enabled to hear speech, under amplified conditions, almost perfectly. Dr. Ewing stressed the fact that these results were obtained under laboratory conditions—it is clearly unlikely that so favourable an effect would be found when using any of the easily portable aids to hearing at present available. It must also be stressed that in these experiments, background noise, so evident when using a normal hearing aid, where it arises from defects inherent in the apparatus itself as well as from the more important source of the extraneous noise present in any normal environment, has been reduced to a minimum. The installation of the microphone in a sound-proof room, to take but one example of special precautions, would clearly be quite out of the question with a portable deaf-aid.

In the discussion at the end of the meeting Major Tucker, of the R.A.F. Research Establishment, Biggin Hill, raised an interesting point with reference to this paper. When listening to speech at very high intensities, he pointed out, the intelligibility is often lowered by masking of high-frequency (consonant) sounds by low-frequency (vowel) sounds. He suggested the possibility of increasing the intelligibility of much amplified speech by the introduction of suitable high-pass filters into the system. He pointed out that at least an experiment on these lines might be worth trying. Mrs. Ewing disagreed about the desirability of doing this, on the grounds that it might lead to distortion of a partially deaf child's speech. Mr. Littler also disagreed, on the grounds, among others, that if low tones are led to one ear and high tones to the other, a peculiar sensation that the sound is spinning round the head was sometimes experienced.

In his paper, Mr. A. F. Rawdon-Smith discussed somewhat different aspects of deafness. He described an apparatus, installed in the Psychological Laboratory, University of Cambridge, with which it is possible to produce very pure tones of great and controllable intensity, and of frequencies throughout almost the whole of the auditory spectrum. The apparatus is used for investigating the phenomena of experimental deafness, and consists of a beat-tone oscillator, amplifiers and attenuators, together with subsidiary frequency checking and monitoring apparatus; sinusoidal voltages from this equipment are led to a moving-coil ear-piece, situated in a highly sound-proof room. With this equipment, the modification of the normal audiogram by listening to intense pure tones for periods up to five minutes has been investigated. If sufficiently intense, such tones lead to a very considerable, though temporary, loss of acuity. Mr. Rawdon-Smith demonstrated that this acuity loss is not confined to the single ear stimulated—on many occasions a loss of acuity almost as great has been found in the ear nominally unstimulated. This, together with the fact that the losses in both ears may sometimes be temporarily removed or lessened by subjecting the observer to an unexpected stimulus, such as momentarily switching off the lights in the sound-proof room, has led him to the conclusion that these losses, usually referred to as being due to auditory fatigue, are partly of cortical mediation. Undoubtedly, peripheral fatigue losses do occur also, as it is possible to show that, in the mammalian ear preparation, using Davis and Saul's method of recording the electrical activity of the auditory mid-brain, a peripheral sensitivity loss occurs; this has been found using the mid-brain action potential (not to be confused with the Wever and Bray (cochlear) effect) as an index of auditory function. The phenomenon of experimental deafness can be regarded, therefore, as of dual origin—in part peripheral, which may be termed auditory fatigue, and in greater part of cortical mediation, for which auditory inhibition is the preferred terminology.

At the end of his paper, Dr. Ewing produced interesting evidence that such partially deaf patients as he has tested are immune from either of these effects; in short, the production of temporarily increased deafness in the already deaf, by listening to loud pure tones or to much amplified speech, even for relatively long periods of time, is impossible.

It is regretted that exigencies of space do not permit of a more detailed discussion of the remaining two papers. If the author has devoted overmuch

space to those already considered, it is only because he is necessarily more familiar with that material.

Dr. P. M. T. Kerridge dealt with the history and causes of deafness in London children in schools for the deaf. It is interesting to note from her analysis that, in the severely deaf group, almost half had been deaf from birth. Miss E. L. S. Ross discussed and analysed the results of an experiment in which a short story was read to two small groups of partially or severely deaf children, first without and secondly with an electrical aid of commercial manufacture. The children's reproductions of this story were marked according as they had, for example, grasped or missed the point, or understood or misunderstood the name of the central character. She showed that only with some of the children was a partial improvement of understanding secured by these means.

A. F. RAWDON-SMITH.

Ability, Opportunity and Social Status

IN a paper entitled "Ability and Educational Opportunity in Relation to Parental Occupation", which appears in the *Sociological Review* (27, No. 3, July 1935), J. L. Gray and Pearl Moshinsky bring forward evidence to show that the children of the less prosperous social classes lack the opportunity for higher education available to the equally able children of the financially prosperous classes. The investigation on which the evidence is based was carried out on nearly 9,000 children, between the ages of 9 years and 12 years 6 months, drawn from primary, post-primary (including central), grant-aided secondary, private, and preparatory schools in the London area, during the year 1933–34. Individual ability was assessed by the Otis Advanced Group Intelligence Test (Form *A*), and each child was questioned individually regarding parental occupation.

The authors point out that every attempt at morphological classification in social orders presupposes a social philosophy and a knowledge of the causes of social differentiation. The classification finally adopted by them represents a compromise between several current systems. The basis of group differences is taken as the nature of the work performed, but is modified "where it seemed advisable" by combination with differences in average income and in social status: the six main groups thus obtained are relatively homogeneous. They are: (*A*) Employing and Directive Classes; (*B*) Professional Classes; (*C*) Minor Professional and Other Highly Skilled Occupations; (*D*) Clerical and Commercial Employees; (*E*) Manual Workers; and (*F*) Miscellaneous Workers and Unknown Occupations.

The significant differences in educational opportunity between these socio-economic categories, revealed by the final analysis, certainly confirm the authors' belief that the groups do constitute real socio-economic strata.

It is evident that this classification correlates to some extent both with parental intelligence and with nurtural and environmental factors in the life of the child. The acceptance of the genetic evidence that highly intelligent parents tend to produce highly intelligent children, or the acceptance of the doctrine that nurture is the dominant factor in intellectual development, leads to the expectation of a small positive correlation between the intelligence of the child population examined and the parental socio-economic status. The value found by the authors is $0{\cdot}25 \pm 0{\cdot}008$, a value which is, however, too small to be used diagnostically. This value compares favourably with the value 0·28 found by Duff and Thompson* in an investigation of the parallel problem in Northumberland ten years ago. As the authors state (but not only for the reasons quoted) it is unwarranted to assert, by reason of the existence of the positive correlation, that intelligence is causally related to parental socio-economic status.

Some of the results of the primary analysis deserve special reference:

(1) In all cases, the children of teachers of every kind exceed the mean of the social group of highest intelligence. This is, perhaps, not surprising in view of the construction of the test used to obtain differentiæ.

(2) The children of the 'larger business owners and higher executives group' are significantly inferior in mean intelligence to those of the professional classes. Nearly every other investigator has arrived at this conclusion.

(3) It is probable that children of manual workers engaged in the newer industries, where, for example, considerable mechanical ability is demanded, are superior in mean intelligence to those of all manual workers.

(4) The children of unskilled workers form a remarkably homogeneous group.

In the ultimate analysis of their material, the authors make a comparative study of the distribution among the various social orders of the opportunity for higher education and of the corresponding distribution of high ability, that is, ability to benefit from higher education, the lower level being taken at 130 *I.Q.* on the Otis scale or 120 *I.B.* (Index of Brightness) on the authors' scale. As a source of children of high ability, the 'manual workers group' is the largest numerically, although it contains the smallest percentage of able children within the group. Thus, 58 per cent of the children of the 'professional classes group' possess ability, and 23 per cent of the children of 'manual workers group' are equally able; but in terms of the ratio of able children in the group to the total of all able children, these figures are 5 per cent and 50 per cent.

The discrepancies between ability and opportunity are shown by the following figures: 95 per cent of the able children of the 'professional classes group' have the opportunity for higher education; 48 per cent of the able children of the 'clerical and commercial employees group' have the same opportunity; only 25 per cent of the able children of the 'manual workers group' receive the same facilities. Opportunity for higher education is wasted most by the children of the 'larger business owners and higher executives' and of the 'professional classes groups'. There are 49 per cent of the former and 35 per cent of the latter, in each group, with opportunity but

* *Brit. J. Psychol.*, 14, Pt. 2; 1924.

without ability. In the case of children selected by competitive examination at the age of 11 plus, only 1·0 per cent have the opportunity for higher education without having the ability to benefit by it.

These figures reveal striking differences between the educational opportunities available for children of equal ability but of parents of different social status; and these differences are inherent in the present social system. That is to say, they belong to nurture and not to nature. It might be added, in comment, that the validity of these results depends on the extent to which the intelligence test measures the ability of the child to benefit from the higher education of the type provided in secondary schools. This is a matter which some educationists would be prepared to debate. W. F. FLOYD.

Tell el-Amarna, 1934-5

AN exhibition of finds from Tell el-Amarna, results of the Egypt Exploration Society's expedition during the season 1934–5, opened at the rooms of the Palestine Exploration Fund, 2, Hinde Street, London, W.1, on September 16, and will remain on view until October 12. Further progress has been made in the excavation of the Royal Palace. Its total length has not yet been ascertained, as exploration has not proceeded beyond the modern road, but it is expected that it will fall not far short of a kilometre.

Operations of the season concentrated on the great hall at the south end of the building, the harem quarter, and the state approach, paved with plaster, which runs on the western side of the harem to the 'Broad Hall'. Advantage was also taken of an opportunity to make a record in tracings and photographs of the sculptured reliefs in the Royal Tomb, which lies in a valley about four miles away. This is the burial place of the young Princess Maketaten, one of the daughters of Akhenaten (1387–70 B.C.), religious reformer and builder of Tell el-Amarna. No complete record of these reliefs has been made before, and owing to the fitting of a new doorway, the opportunity will not recur. The drawings from the tracings have not yet been completed; but the series of photographs, which show the representations of intimate scenes of mourning, including a visit of the Royal Family to the temple, forms part of the exhibit of plans and photographs, which illustrate the progress of the excavations and the character and extent of the building.

Although the finds of the season included several of striking interest, the total number of exhibits is not large. This is due to the fact that a large amount of the expedition's time was absorbed by the deep digging necessitated in the area of the approach way to the 'Broad Hall'. Here a large building, called the 'Shining of the Aten', and part of the approach had been demolished early in the reign of Akhenaten. The whole area had then been filled in with sand to a depth of ten feet and levelled to form a parade ground.

In this filling were found many fragments of the sculpture of the original building, which could not be used elsewhere. Hence the sculptures have preserved all their freshness. Among the selection shown are some singularly striking examples of graphic representation, such as, in particular, spirited horses, soldiers and servants bowing, a fine royal head, and two heads with arrogant expression, here labelled 'priests'. The approach way itself has yielded thousands of fragments of the rows of huge granite and quartzite statues with which it was adorned. These were systematically broken up at the time of the destruction of the city after the death of Akhenaten and the overthrow of his reformed religion.

In the harem quarter, with its garden surrounded by a colonnade carved with festoons of birds, one of the most notable finds was the model of a fish in gold plate, which may have formed a part of the decoration of a formal pond, or have been a royal toy. It is shown only by a photograph, the original remaining in Cairo. One of the most interesting portions of the Palace as yet explored is the great hall at the south end of the building. Its vast roof was supported by a forest of brick piers, and it was decorated with faience tiles. Complete examples of these are now shown for the first time. They show naturalistic flower designs with white daisies in faience inlaid. It is hoped that it may be possible to complete the excavation of the Palace in the coming season. This, however, must depend entirely upon the extent to which further financial assistance towards the cost of excavation can be obtained from subscription by the public.

The Bihar Earthquake of 1934

SOON after the occurrence of this great earthquake on January 15, Dr. J. A. Dunn and three assistants were sent to the areas chiefly affected. A preliminary report on the earthquake by Messrs. J. B. Auden and A. M. N. Ghosh has recently been published (*Rec. India Geol. Surv.*, 68, 177–239; 1935). A brief report has also been written by Mr. N. Nasu (*Bull. Earthq. Res. Inst.*, 13, 417–432; 1935), who spent seven weeks during the following summer in the central district.

Owing to the occurrence of the earthquake at about 2.13 p.m., the loss of life was much less than might have been expected from the damage to property. Including Nepal, more than 10,000 lives were lost, mainly in the crowded towns of Monghyr, Muzaffarpur and the Nepal valley. The isoseismal of highest

intensity (10, Mercalli scale) covers three tracts. The largest is bounded by an ellipse about 80 miles long from east of Motihari to Madhubani and about 20 miles wide. Two much smaller areas lie near Katmandu and at Monghyr, the total area enclosed within the isoseismal being 1,300 sq. miles. Important destruction to property was confined within an area of 31,000 sq. miles. The shock was felt near Madras, at Dharwar and, according to pilgrims, at Lhasa. At about the same time, a shock was felt in the extreme south-west of India, but this was not directly connected with the Bihar earthquake. The total disturbed area was about 1,900,000 sq. miles.

Surface undulations were seen by a great number of observers. It is difficult at such a time to estimate the dimensions of these waves, but, according to one observer at Muzaffarpur, the distance from crest to crest was about 5 ft. and the height of the waves about 6 in. The maximum acceleration was determined at several places by means of West's formula, the highest figure given being 3,270 mm. per sec. per sec. at Monghyr. The corresponding amount for the Mino-Owari earthquake of 1891 was 4,300 mm. per sec. per sec. The amplitude of the movement was 12 in. at Muzaffarpur and 5·2 in. at Katmandu.

One of the most remarkable features of the earthquake is the wide area over which sand and water were ejected from fissures and vents. Indeed, it is doubtful if the area has been equalled in any other known earthquake, for it amounted to about 18,000 sq. miles within the isoseismal 8. As a rule, the rise of sand and water seems to have taken place after the main shock had subsided, sometimes by as much as several minutes. The greatest height reached by the spurts of water was 6–8 ft. In places, the surface was so completely riddled with sand-vents that small areas might be compared with boiling porridge. The closeness of the vents and the wide area covered by the sand suggest that its origin was at no great depth below the surface. According to Mr. Nasu, the deposit of sand was in most places thin, the depth exceeding one foot within an area of not more than 300 square miles.

The ejection of sand attained its maximum within and near what has been termed the *slump belt*. This is a band within the isoseismal 9, covering about 4,700 sq. miles in Bihar and also including portions of Nepal, in which houses were tilted rather than crumbled and the subsidence of the ground was marked. Two lines were re-levelled by the Survey of India, and it was found that the area of subsidence of one foot or more coincides approximately with the slump belt. It may be a zone in which the alluvium was shaken down by the earthquake to a slightly lower level.

The epicentral area enclosed within the main portion of the isoseismal 10 lies about 50 miles to the south of the main boundary fault. Whatever movement, if any, occurred along this thrust plane below the surface, no signs of displacement were detected at its outcrop. It seems probable, therefore, that the movements responsible for the earthquake originated some distance to the south of the boundary fault and along thrust planes that are now concealed by the Gangetic alluvium. The two detached portions of the isoseismal 10 about Katmandu and Monghyr may be due to displacements relieving subsidiary zones of strains in these two areas.

Science News a Century Ago

J. D. Forbes on the Puy de Dôme

On September 22, 1835, J. D. Forbes wrote to his sister: "Clermont seems to me the most pleasantly situated of all the large towns of France which I have seen. It is perched upon an eminence rising from an extensive and fertile plain, which forms a sort of bay amongst the hills which surround it for two-thirds of the horizon. These hills are, for the most part, connected with a plateau or table-land of granite, from which the volcanoes rise; and of these, the Puy de Dôme, the highest and most noted, is conspicuous from Clermont, being about the distance of the nearest Pentlands from Edinburgh, and greatly resembling some of them in shape. . . . The Puy de Dôme was the first mountain up which a barometer was carried, at the suggestion of the famous Pascal, and I ascended it fully as much in reverence for his memory as on any other account. He was a most remarkable man; and as he was a native of this place, I hoped to have obtained some new particulars about him, but in this I have failed".

Cost of University Education

In a letter to *The Times* dated September 22, 1825, "Justus" said: "I am a great admirer of our old Universities and consequently I am anxious that a misrepresentation which is abroad should no longer be unnoticed—I mean an impression relating to the expenses of education there. The charges for what actually constitutes the education are £2 10s. per term or £7 10s. per annum at Cambridge. This charge comprises all the fees, which at the London colleges amount to £21 at the least, to say nothing of the necessarily superior education which may be obtained at the former arising from greater competition, access to the libraries (in which advantage London is very deficient), and those incentives to study which a better situation and greater quiet naturally generate. The expense of board and lodging are very moderate indeed; and I do not hesitate to assert that any young man may secure every advantage which those noble institutions can bestow at an expense of, at the very utmost, £30 per term, or £90 a year".

Naval Architecture in Great Britain

In 1832 Captain (afterwards Rear-Admiral Sir) William Symonds (1782–1856) was appointed to succeed Sir Robert Seppings (1767–1840) as surveyor of the Navy. He held the post for sixteen years, but often was criticised for his actions. On September 23, 1835, *The Times* said: "We have much satisfaction in announcing to the nation that the present disgraceful state of English naval architecture is likely to become the subject of a formal, and we trust, serious and candid inquiry in the next session of Parliament. Mr. G. F. Young has placed upon the order-book of the House of Commons the following notice of motion:—'That a select committee be appointed to inquire into the system at present adopted in the construction of ships for His Majesty's navy; to report how far that system is calculated to insure for the public service the advantages of scientific and practical knowledge of naval architecture, and of improvements in naval construction; and to suggest the best means for submitting to the test of impartial examination and fair competition

the relative qualities of ships constructed on the plans of different naval architects'. Such an investigation is most imperiously demanded, and it will be as important as it will be beneficial to the nation, if properly conducted and carried on without reference to the interests of individuals in office, but on the contrary, with an entire disregard to everything but the attainment of the truth. . . ."

Death of Antide Janvier (1751–1835)

ON September 23, 1835, Antide Janvier, one of the cleverest horologists of the eighteenth century, died in the Hôtel-Dieu in Paris at the age of eighty-four years. He was born on July 1, 1751 at St. Claude (Jura). From an early age, he showed remarkable mechanical skill, and, when still a youth, made a model representing the motion of the moon which Berthoud referred to in his "Histoire de la mesure du temps". At twenty years of age he constructed a fine planetarium. After spending some years at Verdun, where he married, in 1784 he went to Paris where Lalande recommended him for the post of horologer to the king, and where he met with encouragement from the Academy of Sciences. He was deprived of his emoluments during the Revolution, but after the Terror, he was placed in charge of a school of horology, and was well known as a successful teacher. In 1802, he was awarded a gold medal for an astronomical model declared to be the cleverest made during the eighteenth century. Devoted more to his art than to the making of money, his last days were passed in poverty. He published several works including a "Manuel chronométrique", 1810, and his "Recueil des machines composées et exécutées par Ant. Janvier", 1827. After his death, a subscription was opened to raise a monument to his memory.

Societies and Academies

PARIS

Academy of Sciences, July 29 (*C.R.*, 201, 309–368). GABRIEL BERTRAND: Observations concerning the contributions by the atmosphere of sulphur to arable soils. Results of a series of determinations of sulphur as sulphate in rain water collected at Paris, 1931–1932, and of one year at Grignon, 1934–1935. The latter figure, although small, is sufficient to meet the requirements in sulphur of most cultivated plants. CHARLES NICOLLE and J. LAIGRET: Vaccination against yellow fever by the living amaril bacillus, dried and coated. The dried material was coated with either yolk of egg or olive oil before inoculation. Ninety-one persons were inoculated: there was no local reaction and no anaphylactic trouble. A single vaccination by this method replaces three inoculations by the current method. EMILE MATHIAS: Dauzère's theory on the conductivity of the air in regions exposed to lightning. E. J. GUMBEL: The greatest age, distribution and series. Statistical study of tables of survival. ALFRED LIÉNARD: The problem of the oblique derivative in the theory of potential. PAUL MONTEL: A formula of Weierstrass. PAUL BOURGEOIS and J. F. COX: The origin of comets. BASILE FESSENKOFF: A method of evaluation of the absorption in galactic nebulæ. FERNAND BALDET: The resolution of Nova Herculis, 1934. According to an observation made at the Lick Observatory on July 4, Nova Herculis is double, with two components with 0·2 in. apparent distance. This is confirmed by observations made at Meudon on July 23 and 24. FRANÇOIS CANAC: The study of intercrystalline corrosion by the method of luminous diffusion. D. G. DERVICHIAN: The interfacial tension between two liquids. ARCADIUS PIEKARA and MAURICE SCHÉRER: New experiments on the magnetic change of the dielectric constant of liquids. The large Bellevue electromagnet has been utilised in the study of the effect of the magnetic field on the dielectric constant as a function of the intensity of the magnetic field, the wave-length, and the angle between the electric and magnetic fields. E. FRIEDLANDER: The absence of natural β-radioactivity of beryllium. All commercial beryllium salts possess a marked radioactivity, but this is removed by careful purification, and it would appear that the pure products possess neither β- nor γ-radioactivity. MLLE. NIUTA KLEIN: The variation of the refractive index of non-annealed glass as a function of the time. The experimental results described appear to indicate that the variation of the refractive index with time is due to the transformation of the β variety into the α variety of the glass, a transformation prevented by rapid cooling. MLLE. MARIE LOUISE DELWAULLE: The system bismuth iodide–ammonium iodide–water. ANDRÉ DE PASSILLÉ: The existence of a series of ammonium orthophosphates and orthoarsenates. G. DEDEBANT, PH. SCHERESCHEWSKY and PH. WEHRLÉ: The theory of the general circulation of the atmosphere. The average field of temperature. MME. ODETTE THELLIER: Condensation nuclei and particles in suspension in the atmosphere. PAUL CHABANAUD: The vomer, the ethmoidian complex and the peripheral path of the olfactory nerves of the soleiform Teleosteans. TIFFENEAU and BROUN: The microdetermination of ethyl, propyl and isopropyl bromides in the tissues of animals anæsthetised by these substances. OLIVIER GAUDIN: The comparative toxicity of the pyrethrines towards different classes of animals. Pyrethrines are highly toxic to Crustacea; with other animals, the toxic action is variable. MAURICE ROSE and HENRI BERRIER: The appearance of substances functioning as plant auxins, in the course of the development of *Discoglossus pictus*. JACQUES BENOIT: New experiments relating to the stimulation by light of the testicular development in the duck. CLÉMENT COURTY: The magnetic micro-estimation of iron in the blood. MAURICE PIETTRE: The physico-chemical action of some electrolytes on the myxoproteid of the blood serum. SERGE METALNIKOV and L. Y. MENG: The utilisation of micro-organisms against mole-crickets (*Gryllotalpa vulgaris*).

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, 21, 413–506, July 15). FRANZ BOAS: The tempo of growth of fraternities. Data from the Hebrew Orphan Asylum in New York show that the brothers and sisters of children classified as tall, medium or short at a given age fall also into these groups, indicating inheritance of tempo of growth. Jewish immigrants into the United States measured in 1910 and born between 1850 and 1890 do not show the increase of stature generally characteristic of European populations during the past century, but their children often living under poor conditions in New York, show progressive increase in stature, indicating that environment is also a factor in determining bodily

form. P. VAN DE KAMP and A. N. VYSSOTSKY: Analysis of 18,000 proper motions derived at the Leander McCormick Observatory. Some general results obtained from this survey of stars between magnitudes 7½ and 14 are that the solar apex differs by 15° from that derived with respect to the bright stars, due possibly to a higher percentage of high velocity stars among the apparently faint stars, that the secular parallaxes are somewhat larger in northern than southern galactic latitudes and that parallaxes of groups of fainter stars in the Milky Way are larger than previously supposed, indicating heavy obscuration near the plane of the Milky Way. FRED M. UBER and T. H. GOODSPEED: Micro-incineration studies. (1) Localisation of inorganic elements in plant cell-walls. A special electric furnace for micro-incineration is described. Sections of tissues are held in position by a gelatin smear hardened by formaldehyde vapour. Photomicrographs of sections before and after incineration are given. They show absence of ash in intercellular substance, and limitation of mineral elements to the 'middle lamella' of the cell-wall. H. C. SHERMAN and H. L. CAMPBELL: Relation of food to regularity of nutritional response. Rats reared on a diet better than 'adequate' show more rapid growth, more successful reproduction and extension of the adult life-cycle; these responses occur with less variability than the responses of rats on an 'adequate' diet. M. A. BIOT: Quadratic wave equation: flood waves in a channel with quadratic friction. A mathematical investigation of the type of flood wave caused by the bursting of a dam. An exact solution of the equation of propagation of waves with quadratic damping is found. High amplitude waves are more quickly damped, and the damping effect depends on the volume of the wave and the friction coefficient of the channel. TH. DOBZHANSKY: Maternal effect as a cause of the difference between the reciprocal crosses in *Drosophila pseudo-obscura*. GEORGE D. SNELL: The determination of sex in *Habrobracon*. In this parasitic wasp, as in other Hymenoptera, the males normally arise from unfertilised eggs (a haploid generation). After inbreeding, however, males may arise from fertilised eggs (diploid) and are commonly sterile. The hypothesis is advanced that there are a number of pairs of factors, probably on different chromosomes, which when heterozygous cause diploid zygotes to become females. ALAN L. MITCHELL: The inheritance and linkage relations of kinky coat, a new mutation in the Norway rat. This character is inherited as a simple Mendelian recessive, and since it is not linked with other known characters, its gene appears to lie in a seventh chromosome. CHESTER STOCK: Titanotheres remains from the Sespe of California. The remains were found in the uppermost Eocene horizon at one particular locality alone. HASSLER WHITNEY: (1) Differentiable manifolds in Euclidean space. (2) Sphere-spaces. G. A. MILLER: (1) Groups which are the products of two permutable proper sub-groups. (2) Largest groups determined by the squares of their operators. SAUNDERS MACLANE: Abstract absolute values which give new irreducibility criteria. W. SEIDEL: On a metric property of Fuchsian groups. NORMAN E. STERNROD: On universal homology groups. OSWALD VEBLEN: A conformal wave equation. A differential equation in generalised four-dimensional conformal geometry, somewhat analogous to the Dirac equation for the electron in classical relativity. A. G. JACQUES: The kinetics of penetration. (10) Guanidine. Plotting the rate of entry of guanidine into cells of *Valonia* against external concentration of guanidine suggests that entrance is preceded by a reversible action between this base and an acidic constituent of the protoplasm. HENRY BORSOOK: The correlation between excess calories and excess urinary nitrogen in the specific dynamic action of protein in animals. Further data are quoted in support of the view that a steady state is attained between the increase in energy metabolism and urinary nitrogen within four hours after the ingestion of protein. DICKINSON W. RICHARDS, JR., ANDRÉ COURNAND and ISRAEL RAPPAPORT: Relation of the regulatory mechanism of respiration to clinical dyspnea. Dyspnea, or distress, referred to the act of breathing, whether due to physical exertion or pathological conditions, is due to disturbance in the mechanical functioning of the organ of breathing. It is associated exclusively with sensory impulses from chest and lungs; and separated from the physical chemistry of respiration. CHARLES A. KOFOID: On two remarkable ciliate Protozoa from the cæcum of the Indian elephant. Two new genera of relatively large ciliate Protozoa are described. Both have several spirally curved ciliary zones arranged in a secondary bilateral grouping instead of the single dorsal zone in other members of the family, and show other advanced characters. The evolution of structural complexity in the protozoan parasites of herbivorous animals seems to have proceeded parallel to that of their hosts.

International Control of Aviation

THE prominence which the question of air raids and air defence is receiving affords a timely reminder both of the extent to which aviation is rather an international than a national problem, and of the way in which this new power of flight has become rather a menace than an aid to civilisation. A memorandum*, and also one of the six projected handbooks dealing with air raid precautions, have recently been issued by the Air Raid Precautions Department of the Home Office†. In a general preface to the handbook it is explained that measures for safeguarding the civil population against the effects of air attack have become a necessary part of the defensive organisation of any country which is open to air attack, and that the need for them does not arise from any belief that war is imminent. The risk of attack from the air, however remote it may be, is a risk which cannot be ignored, and preparations to minimise the consequences of such attack cannot be improvised on the spur of the moment, but must be made, if they are to be effective, in time of peace.

The handbooks are designed to describe a scheme of precautions which it is hoped would prove effective in preventing avoidable injury and loss of life or widespread dislocation of national activities, and endeavour to give the best available information on methods of passive defence against air attack. The handbook before us is intended primarily for the use of those who in a war emergency would be engaged on first-aid services for the civil population, especially members of the St. John Ambulance Brigade, the St. Andrew's Ambulance Association and the British Red Cross Society. It contains a sufficient account of the chemical agents likely to be used and the methods by which they might be distributed to enable such persons to appreciate the dangers to which they would be exposed, as well as adequate information on general principles with regard to protection against gas. Steps to be taken for the protection of rooms, etc., against gas, the use of respirators and protective clothing and the treatment of various types of casualties are detailed, as well as measures for the decontamination of personnel and material.

Both the matter and the general principle underlying the publication of these handbooks have already received severe criticism. In the first place, it has been pointed out that the precautions described in the handbook are quite inadequate to confer any real protection. At a recent conference in London it was strongly maintained that it would be impossible adequately to protect a large civil population during a gas attack, or prevent them receiving injuries afterwards from, for example, mustard gas lingering in different places.

It is true that the handbook only professes to deal with avoidable injury, but any attempt in this way to minimise risk may easily create a feeling of false security and encourage the belief that the danger can be entirely avoided. This risk has probably been responsible for opposition from those who emphasise the impossibility of affording civilians the same protection as the services because of the enormous cost. A statement signed by Sir F. G. Hopkins and a number of

* Air Raid Precautions. Memorandum No. 1: Treatment of Casualties and Decontamination of Personnel. (Issued by the Home Office, Air Raid Precautions Department.) Pp. 15. (London: H.M. Stationery Office, 1935.) 4*d*. net.

† Air Raid Precautions. Handbook No. 2: Anti-Gas Precautions and First Aid for Air Raid Casualties. (Issued by the Home Office, Air Raid Precautions Department.) Pp. 110. (London: H.M. Stationery Office, 1935.) 6*d*. net.

other men of science, and issued by the National Peace Council, takes this view. Adequate defence must provide security against the simultaneous, and not merely the independent, use of high explosive bombs, incendiary bombs and gas attacks. It is necessary to insist that, however wise the proposed measures may be in themselves, the only adequate defence against air warfare is the abolition of war itself, and to point out the danger of allowing precautions or palliatives to divert attention from the main objective.

It is very generally accepted that abolition of national military and naval forces could not be achieved without the international control of civil aircraft, and the more reasonable it is for the British Government or any other Government to consider the means of protecting the civil population from air attack, the more imperative it is that the means of introducing international control should be explored. Equally desirable is the careful examination of the practicability of establishing an international air police force such as has received forceful advocacy of late.

The many questions which arise out of these proposals, such as the relation of an international force to the League of Nations, the technical difficulties to be overcome or the methods of preventing misuse of civil aviation, merit close and scientific study; it may well prove that along these lines will be found the only adequate safeguard and security for all nations. Scientific workers have a special responsibility for assisting in bringing to bear on all such questions an unprejudiced mind and the careful and impartial scrutiny of every factor involved which should be characteristic of the scientific mind.

Inevitably the study of the problem of the air from this point of view leads to the consideration of the whole problem of the future peaceful development of civil aviation. It would be difficult indeed to find a more signal example of the frustration of science than is afforded by aviation, and it is inconceivable that the development either of an international air police force or of international control of civil aircraft could be more inimical to development than the national jealousies and obstructions hitherto in vogue. The effect of these was strikingly demonstrated in the able report on the economics of air transport in Europe recently submitted by M. Henri Bouchée to the special sub-committee of the Air Transport Co-operation Committee of the League of Nations.

The substitution of a single International Air Board of Control under the League of Nations for the twenty-six different controls now exercised by the separate States of Europe alone would remove many hindrances to the development of civil aviation, including restrictions on design, flying lanes and prohibitions to engage in entrepôt trade, and would provide far greater stimulus than is possible under the present conditions of national sovereignty. The powerful plea advanced by M. Bouchée for collective action, calculated on a European scale to meet European needs and based on strictly economic lines, utilising subsidies in a manner enabling air transport to establish itself once and for all, and affording aviation the freedom which is natural to it but which as yet it has neither demanded nor received is, however, only one aspect of the question.

The technical problem in civil aviation is equally important, and here the whole development of civil aviation has been warped from the start through the influence of the War. But for that factor, as Colonel Moore-Brabazon has pointed out, aviation might have developed along different lines, quietly and efficiently, and civil aviation might have played the important part it is meant to do in intercommunication, the military side lagging behind. As a result of wartime development, civil aviation has become no more than an off-shoot of the great military organisations in various countries, and only in Great Britain and the United States can it be said that aviation has been allowed to develop free from direct military influence.

The Diesel engine provides a conspicuous example of the ulterior effect of military influence on civil aviation. From the civil point of view, the Diesel engine has many advantages, notably in burning a fuel of high flash-point and the price of which in Great Britain is less than half that of petrol. This engine, however, is of little interest for military purposes because its performance is not so good as that of the petrol engine and it is also heavier. Since the major outlook for a new type of machine depends on its possibilities for military uses, there is little inducement for the manufacturer to develop the Diesel engine, although there is no type of transport for which the petrol engine is more fundamentally unsuitable than for the aeroplane with its load of inflammable fuel.

If civil aviation is to develop to the full and render its due service to mankind, it must be

freed completely from military influence, whether technical or economic. The root of the problem lies in the conflict between the conceptions of sovereignty of the air and freedom of the air. Only as the latter conception triumphs can humanity hope that aviation will progress as an instrument not of war but of peace. Scientific workers can never rest content with the mere precautionary methods outlined in the handbooks and policy of the Air Raid Precautions Department. They can indeed contribute something to see that the precautions, so far as they go, are technically sound and are fairly and not unfairly criticised. They fail in their duty, however, if they do not also continue to point out that the only adequate defence or security against air attack lies in the abolition of war itself and in liberating aviation from the bonds imposed on it by the narrow nationalism expressed in the Air Convention of 1919, and clothing it with the freedom of service in which were conducted those technical and scientific investigations which first gave it birth.

The Changing World of the Ice Age

The Changing World of the Ice Age

By Prof. Reginald Aldworth Daly. (Yale University: Mrs. Hepsa Ely Silliman Memorial Lectures.) Pp. xx+271+8 plates. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1934.) 22*s*. 6*d*. net.

IN this book Prof. Daly has reprinted the Silliman Lectures for 1934 which he delivered at Yale University to "an audience with a varying knowledge of the facts and principles of geology". But to make the book of greater value to more serious students, the lectures have been somewhat expanded. The author had a threefold aim: (1) to picture the remarkable effects of the Pleistocene glaciations and deglaciations upon the sea-level all over the world; (2) to illustrate some of the no less extraordinary changes in the geography of the regions that were heavily glaciated during the Ice Age; (3) to discuss the behaviour of the solid earth when it was loaded with the ice-caps and then relieved of those loads by melting and evaporation.

The book is divided into seven sections. A very large amount of material has been used, and many of the facts and instances cited are not easily found elsewhere because of the difficulty of access to many of the publications and the difficulty of reading some of the less-familiar languages in which they are written. At the outset, it may be said that the author accepts a number of hypotheses which some observers are not prepared to adopt, but he never misleads his readers into the supposition that these views are of unanimous acceptance.

In the first section, past and present ice-caps, their measurement and weights are described. Then the sequence of glaciations is considered and the author, while accepting the four glaciations of Penck and others, in Europe and America, lays stress upon the long duration of the second interglacial phase and its separation of the first twin glaciation from the second twin glaciation. These two peaks of climatic change in the glaciated tracts corresponded with two major pluvial stages in regions now relatively desert, and also with two major periods of deposition of loess in different continents. These climatic rhythms affected simultaneously the whole surface of the earth. An estimate of the duration of the Ice Age is given as nearly one million years. These considerations lead up to the urgent question of what caused the Ice Age; the author is frankly in doubt and confesses that the subject is still in the state of speculation and remains to him a baffling mystery.

The second section of the book will probably be of greater interest to European readers than are the remaining sections, for it deals with the recession of the Fennoscandian ice sheets; and especially to students of prehistory, for post-palæolithic man has left determinable evidences of sequences of culture in relation to geological changes all round the Baltic shores.

Pleistocene changes in the geography of northern Europe are registered largely by the marks left by the waves of the ocean that kept shifting its level, both up and down, all over the earth. It is not, perhaps, generally realised to what an extent the robbery of water from the oceans during the maximum glaciation depressed the general level of the sea; the author shows that the amount was probably as much as 90 metres all over the earth; and even during the last glaciation, a sinking of some 75 metres was attained. But he warns his readers against supposing that in the warmest interglacial stage the sea-level was higher than it is at present by more than a few tens of metres; and further, that the

strand-lines on the lands cannot be in uniform relation to the surface of the existing ocean because of the earth's elastic and plastic response to the loading and the unloading with ice and water.

The recession of the North American ice is discussed in the third section, and comparison is made with the European phenomena. This chapter may be described as indispensable to students of the Ice Age, and moreover it summarises in some fifty pages the great volume of matter not easily accessible to the student, that has been published in monographs, reports and the like in recent years, while its clearness is increased by an adequate number of good maps and pictures.

The mechanism of the earth's deformation and recoil, especially as regards the effects of the crust's yield to the ice-loads, is dealt with in the fourth section. The author directs attention to the need of distinguishing between the immediate, elastic and the prolonged plastic response to load and release, and prefers the hypothesis of 'punching' to explain the plastic upwarping around ice caps to the 'wave' or 'viscous bulge' theory.

The remaining sections are devoted to the consideration of the high and the low sea-levels of the Pleistocene in areas removed from the glaciated tracts. Special emphasis is placed upon the want of uniformity in heights above sea-level of the abandoned sea-beaches; it is pointed out that there can be no simple criterion of the eustatic emergence "based upon the naïve idea that this process gives strandmarks at constant heights all over the world". But the more recent the eustatic emergence, the fewer are the dangers of mistaking the traces of the corresponding strand-lines on the rocks of continents and islands.

Finally, the effects are discussed of the changes of sea-level upon coral reefs in Pleistocene times, and the 'glacial control' theory of atoll and barrier reefs finds preference to the hypotheses of Darwin and Dana respectively.

The book is thoroughly illustrated with maps and views, and the author is to be congratulated not only on them but also for departing from the too usual practice of giving insufficient references in the text to the illustrations. It is a book of first-class importance and of equal interest, and is written in such concise and clear language that any well-educated boy could understand it.

Everyday Life of Extinct Animals

Vorzeitliche Lebensspuren

Von Othenio Abel. Pp. xv+644. (Jena: Gustav Fischer, 1935.) 24 gold marks.

EXTINCT animals are known chiefly by their fossilised bones, teeth or shells, which afford many clues to their mode of life and reproduction. There are, however, several other kinds of fossils which add to our knowledge of extinct animals as living organisms. Footprints, remains of food, coprolites, traces of disease and accident, and even remains of dwellings, are all most instructive when they are satisfactorily interpreted. These are described by Prof. O. Abel as "Vorzeitliche Lebensspuren" in the handsome volume before us. Here they are discussed critically, with many original observations, and they are illustrated by an unrivalled series of photographs besides drawings and diagrams.

In the first chapter, on reproduction, the most interesting section is that on the young often found within the skeleton of Ichthyosaurians. Prof. Abel concludes that although the majority must be unborn embryos, a few may perhaps have been swallowed as food. The marked discrepancy in size sometimes observed among the contained young seems to justify this conclusion.

The second chapter, which is by far the longest, discusses tracks and footprints and the modes of locomotion which they imply. The interpretation of these fossils is difficult, because so little is known of the tracks of most animals which live now. The conclusions to be drawn from the hand-shaped footprints of *Cheirotherium* from the Trias, which have already been studied by Soergel, and the classification of reptilian footprints by Nopcsa, however, are valuable, and Prof. Abel reviews them in detail. He is of opinion that no undoubted footprints of vertebrates have hitherto been found in Devonian rocks, and he thinks that the *Thinopus* of Marsh is probably a coprolite of a fish. He also points out that some of the Carboniferous footprints have been wrongly interpreted: he would explain the so-called claws of *Onychopus*, for example, as being the marks of runnels of water into the print. It is curious to note that some imprints of the fins of fishes in motion have been preserved in the Jurassic lithographic stone of Bavaria. The tracks of crustaceans and worms are familiar.

The chapter on food and feeding is remarkably exhaustive, beginning with an account of the stomach-contents of the Siberian mammoth and the North American mastodon, and ending with a discussion of the feeding tracks of certain worms. Referring to the remains of land plants found inside the fossil 'mummified' bodies of the aquatic dinosaur *Trachodon*, and sometimes described as the food of this reptile, Prof. Abel advises caution in identifying the stomach-contents within skeletons. *Trachodon* must have fed in the water, and the fragments of land plants were evidently introduced into the fossil with the rock sediment. He also agrees with those who assert that coprolites marked by a spiral valve have never been found in Stegocephalian Amphibia or in Ichthyosauria: he refers all such coprolites to fishes, in which they have often been found.

Among borings and other traces of dwelling places which are described, the most interesting perhaps is the fossil nest of a termite from an Upper Pliocene deposit near Vienna. Among fossil examples of commensal and symbiotic animals, the most curious is *Kerunia*, from the Upper Eocene of Egypt, which seems to be a hydractinian associated with a crustacean. Among indications of injury and disease, the irregular rugosities on the snout of many crocodile-like Triassic reptiles are remarkable. The prevalence of disease among the bears which inhabited the European caves during the Pleistocene period is also interesting.

A brief account of fossil records of death struggles is followed by a final chapter on insects and spiders in amber, which is contributed by Dr. Adolf Bachofen-Echt. Like the rest of the volume, it is illustrated by photographs which are as remarkable as they are beautiful.

From this brief summary it will be seen that Prof. Abel's volume is not only a valuable work of reference in an unusual subject, but is also a stimulating contribution to palæontological research.

Mathematics and Materialism

The Search for Truth

By Prof. Eric Temple Bell. Pp. x+279. (London: George Allen and Unwin, Ltd., 1935.) 7*s*. 6*d*. net.

PHILOSOPHY is a subject of study as earnest and important as any individual science. Prof. Bell apparently does not share this view, however, for in his book, which has the characteristics of a brilliant joke, he simply uses some aspects of the history of science as an occasion to poke fun at philosophy and to launch an attack on philosophers. Thus, he tells us that a considerable part of the efforts of the Greek thinkers "seems to have centred round the verb 'to be' ". And again, that "Aristotle and Plato were presently to prepare the ingenious noose with which the Middle Ages were later to hang themselves; and Euclid was to tie knots around the vital parts of geometry which were to paralyse its creative function for two-thousand years" (pp. 97–98). Or again, that "the theologians of the Middle Ages before the Twelfth Century had built their cathedral of learning and reason" on the first half of Aristotle's logical treatise (p. 143). For him, St. Anselm, Abelard and William of Occam were "incurably logic-mad"; and Duns Scotus deserves immortality on the only count that "his name has passed into the English language in the word *dunce*".

Prof. Bell may dislike speculations that cannot be tested at this moment by experiment; he may even be praised for exposing fourth dimension charlatans; but he certainly does no service to real scholarship by carrying to extremes the process of "debunking", which seems to become a source of inspiration in many quarters, across the Atlantic especially. In any event, he has no right to be misleading as when he endeavours to draw a parallel between the invention of non-Euclidian geometries and the exposition of many-valued logics given by Prof. Lukasiewicz—two branches of knowledge which have neither the same origin nor the same implications.

It would serve no useful purpose to initiate a general argument about a book full of pointless remarks and stripped of all references, until its author takes the trouble of recasting his pronouncements in the habitual forms of a tolerant and well-founded controversy. We should also like him to tell us more about truth, for though he concerns himself, lightly we believe, with the "Search of Truth", all we hear about this important idea is that, for Prof. Bell, an "Eternal Absolute Truth", which has no reference to experience, is of no importance whatever.

With this mere confession of faith, however, materialism will fare no better. Without sharing this particular creed, we can say, nevertheless, that a skilful use of the history of science and the sociological interpretation of mathematics could

have prepared a serious case for materialist science, in spite of the difficulties of experimenting with transfinite numbers, non-Archimedian geometries and many-valued logics. Prof. H. Levy has hinted at such an interpretation in a chapter of "The Universe of Science". A parallel method was also suggested in an article on "Numbers and Numerology" in NATURE of January 20, 1934, p. 80, in which the attempt was made to raise to a higher level the whole problem of the relations of thought and number. Until we are given such an interpretation, it is difficult to acknowledge, as we are invited to do by the publishers of this work, that "materialist science at last has its Jeans". T. G.

Prof. Hans Molisch's Recollections

Erinnerungen und Welteindrücke eines Naturforschers
Von Hans Molisch. Pp. xii+232. (Wien und Leipzig: Emil Haim und Co., 1934.) 10.80 gold marks.

IN this autobiography, written at the instigation of his friends and pupils, Hans Molisch gives us his recollections of a busy and not uneventful life devoted to the pursuit of science. His researches, particularly those into the microchemistry of plants, are well known in Great Britain, but with his personality we are less familiar. His biographical recollections will therefore do something towards our enlightenment.

Born in 1856 at Brünn, now famous as the seat of Gregor Mendel's epoch-making experiments, Molisch learnt, as a boy, in his father's nursery gardens, the methods of cultivating plants, which stood him in good stead when he became a plant physiologist. His training for this career he acquired at the University of Vienna under Julius Wiesner, whose assistant he afterwards became. His first professorial appointment was at the Technical College in Graz, and later he was promoted to the botanical chair in the German University of that town. He has a good deal of interest to tell us of the staff and the students of this university and something too of the ill-feeling which existed between the Czechs and the German students.

In 1897, aided by funds from the Academy of Sciences in Vienna, Molisch undertook a journey round the world, working for some time at the botanical gardens at Buitenzorg. Of his travels, as well as his work, he gives us an interesting account.

On the retirement of Wiesner in 1909, Molisch was appointed professor of plant physiology in Vienna, where he remained until his own retirement in 1928. Here he continued his microchemical investigations, but found his activities somewhat cramped by the absence of experimental grounds. In 1914 he visited England and only just escaped being interned on his return through France. While still holding his professorial chair in Vienna, he was invited to become for two years the director of the New Botanical Department of the Tôhoku Imperial University at Sendai, and on this occasion made his second journey round the world. He tells us a good deal about his stay and his work in Japan, though of course less fully than in the book he published in 1926.

After his retirement from the professorship at Vienna, he was invited to lecture and work at the Bose Institute in Calcutta, and the account of his work there will be read with interest. Molisch's account of the conditions in India and its people is worth perusal.

The author concludes his book, which contains his portrait and a number of other illustrations, with some reflections on 'life', stating his opinion that living matter has never arisen from lifeless inorganic matter, and his belief that the origin of life is at the present moment and perhaps will always remain insoluble—a riddle of the universe.

The Biology of Flowers
By W. O. James and A. R. Clapham. Pp. viii+116+41 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1935.) 8*s*. 6*d*. net.

THIS unusual book should prove valuable in inspiring enthusiasm for what is so often made a very dull branch of botany to the average student. Each flower is carefully described in readable language, so that, once having worked through the book, the student can turn to his more compact Flora well armed and ready to follow floral taxonomy with interest. The diagrams are singularly attractive, but there seems no excuse for their being reproduced on such a large scale, since most of them are either floral diagrams or halves of flowers. Nearly all could have been reduced to a quarter of their present size, without detracting from their usefulness; thus reducing considerably the size and possibly the price of the book.

(1) Theoretical Physics
By Prof. Georg Joos. Translated from the first German edition by Dr. Ira M. Freeman. Pp. xxiii + 748. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1934.) 25*s*. net.

(2) Lehrbuch der theoretischen Physik
Von Prof. Dr. Georg Joos. Zweite Auflage. Pp. xvi + 676. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1934.) 24 gold marks.

(1) THE first edition of the book by Dr. Joos appeared in 1932 and was favourably noticed in NATURE, **131**, 221; 1933. The English edition now before us shows every sign of having been prepared with great care, and is written in clear and straightforward language, which is unfortunately more than can be said for many translations from the German. Only minor alterations and corrections have, apparently, been made in preparing the English version. We can congratulate Dr. Freeman on his very satisfactory performance of a task which we are glad to see accomplished.

(2) The second German edition contains a new chapter on nuclear physics, which consists mainly of a non-mathematical description of the new work on artificial transmutation and the newly-discovered elementary particles. There is also a brief addition concerning the method of magnetic cooling which has been applied with such success by de Haas, Simon and others to obtain exceedingly low temperatures. Otherwise there is little change in this admirable textbook.

It seems a little strange to an English reader that a German cannot bring out even a new edition of a work on theoretical physics to-day without a prefatory reference to the *neues Reich* and the *harter Daseinskampf des deutschen Volkes*, but we suppose that it has its reason. We further note the addition of a glossary explaining 'foreign' terms, in which *Absorption* (*Verschluchung*), *Elastizität* (*Dehnbarkeit*), *Kapillarität* (*Haarröhrchenkraft*) and such-like non-Prussian words, are translated into the new German, although these 'foreign' words appear in the articles in Gehler's "Physikalisches Wörterbuch" of more than a hundred years ago. Merkwürdig!

E. N. da C. A.

(1) Grundriss der Cytologie
Von Dr. Lothar Geitler. Pp. viii + 296. (Berlin: Gebrüder Borntraeger, 1934.) 19.20 gold marks.

(2) Handbuch der Pflanzenanatomie
Herausgegeben von Prof. K. Linsbauer. Allgemeiner Teil: Cytologie (Die Organe der Zelle). Band 2: Allgemeine Pflanzenkaryologie. Hälfte 1: Der "Ruhekern". Von Prof. Dr. Georg Tischler. Zweite Auflage. Pp. xx + 630. (Berlin: Gebrüder Borntraeger, 1934.) 64 gold marks.

(1) THE number of cytological books is rapidly increasing. The two before us, while both morphological, are almost entirely different in their contents. The work by Geitler aims, on the whole successfully, at giving a statement of the fundamental facts of general cytology, and cites results from plant and animal cells with equal frequency. Its six sections deal respectively with cell morphology, cell division, nuclear division, fertilisation, meiosis, and cytology in relation to heredity. The work is illustrated with 209 figures, some of which are original, a number being photomicrographs. Some of the recent studies of chromosome structures are given, including photographs of the salivary gland chromosomes in the *Simulium* larva. Selected studies are given from the Protozoa, Algæ and other groups of plants as well as the higher plants and animals. This book will serve a useful function as an introduction to the modern problems connected with cytology.

(2) Prof. Tischler's work is a second edition, the first having appeared in 1922. It deals exclusively with the resting plant nucleus, being an exhaustive review with citations of all the relevant literature. The present edition is largely increased in size, the number of publications cited having risen from 1,909 to 3,883, a striking index of the rapid increase in cytological literature. The topics considered are arranged under such headings as the general morphology and chemical organisation of the resting nucleus, the morphology of network, karyolymph, nucleoli, protein crystalloids, the nuclear membrane and exchanges through it, multinucleate cells, and the relation of the resting nucleus to cell division. This volume will be of permanent value as a work of reference.

Experimental Physical Chemistry
By Prof. Farrington Daniels, Prof. J. Howard Mathews and Prof. John Warren Williams. (International Chemical Series.) Second edition. Pp. xix + 499. (New York and London: McGraw-Hill Book Co., Inc., 1934.) 21*s*. net.

FOR this second edition the authors have largely rewritten their book; alterations in experimental procedure to give higher accuracy, replacement of less satisfactory methods by new ones, and a different treatment of electromotive force and capacity constitute the principal changes.

In Part I, "Laboratory Experiments", each of the fifteen chapters deals with a particular field of physico-chemical work. The experiments are systematically described, each method being preceded by an adequate explanation of the theoretical principles involved, and followed by a summary of the practical applications of the method and suggestions for further work. Under the heading of Apparatus, Part II deals with means and technique necessary for work of a more advanced nature. These operations are grouped under chapter headings of the subjects to which they are most applicable, the order adopted for Part I being repeated in Part II; this, together with adequate cross-references, gives the book added coherence. Part III is concerned with miscellaneous operations, such as calibration, thermostatic control, the determination and influence of errors, which are of value in the conducting of any detailed systematic investigation.

Though the authors make no claim for completeness, this is a well-proportioned and comprehensive guide for both the student and the research worker.

H. K. W.

Speed*

By Prof. B. Melvill Jones

THE reason why a real fluid can leave the surface is now well understood, but the calculation of the precise point at which it will do so is still a matter of great difficulty, over which we are only just beginning to obtain the mastery. It is still true, in the main, to say that the question whether or not a given body will give a good streamline flow can be determined only by experiment, and it is entirely for this reason that it has been found worth while, in the countries interested in aeronautical development, to spend large sums of money on the construction of huge wind tunnels, within which the necessary experiments can be made. Even in these tunnels the question cannot be settled with absolute certainty, and research workers are turning more and more to face the difficult technique of experimenting in actual flight, to determine how nearly the flow about actual aeroplanes approaches the ideal streamline form.

It is, of course, no easy matter to design and make what may be described as streamline aeroplanes. It is necessary first to eliminate such an obvious obstruction to the air as the undercarriage, by pulling it up into the body or wings when in flight. This involves designing a light and strong mechanism which will return the wheels to the landing position and lock them there with well-nigh absolute certainty. The importance of this point strikes one with added force when landing for the first time upon a collapsible undercarriage which cannot be seen from inside the aeroplane. Next, there is the still more difficult problem of cooling the engines without exposing unstreamline objects to the air stream. The problem is especially difficult with the air-cooled engine which is so convenient in other respects: it has been partly overcome by devices known as the N.A.C.A. cowling and the Townend ring, which are placed around the engine to prevent it from deflecting the air stream away from the surface of the body behind it. Then again the pilot must be able to see forward comfortably through a window which does not spoil the streamline form of the body. This is rather easier when there is no engine in the nose of the body, for the pilot can then be placed well forward in a position where there is less danger of his window causing the stream to separate from the body. Finally, it is necessary to ensure that the junctions between the body and the wings and tail are not such as to lead to unstreamline flow, even though these parts separately would behave in a perfectly streamline manner. It is only recently that reliable information on this point has become available and led to designs in which the wings are carefully moulded into the body.

* *Continued from page* 466.

Until two or three years ago, these difficulties were altogether too much for designers and constructors, with the result that the resistance of the average aeroplane at high speeds was many times greater than it would have been with correct streamlining, and speeds of 100 miles per hour or slightly more were all that could be obtained from the power—one horse-power to about 12–15 lb. weight—usually supplied for transport purposes. During the past few years, the speed of the most advanced forms of civil aerial transport has risen from something less than 100 miles per hour to the neighbourhood of 170 miles per hour—the top speeds of the best aeroplanes have, as everyone knows, risen to more than 200 miles per hour, but I am referring to the actual travelling speed. This increase has been primarily due to improvements in streamlining. Secondary developments, such as that of the variable pitch screw and the split-flap wing, have been necessary to enable advantage to be taken of the reduced head resistance without adversely affecting the problem of landing and taking off, but these of themselves could have achieved but little upon the older unstreamline aeroplane.

In the epoch of the imperfectly streamline aeroplane, from which we are only now beginning to emerge, the skin friction on the exposed surfaces contributed so small a fraction to the whole resistance that, even if it could have been eliminated altogether, the speeds would not have increased to any important extent, but, now that it is becoming possible to approach the perfect streamline shape, skin friction provides the dominating contribution to the resistance, and its study with the view of possible reduction of head resistance is transformed from a matter of mainly academic interest to one of supreme practical importance. Here again that curious and insistent urge, which causes the unpractical man of science to study problems for their own sake, without reference to their immediate practical application, has stood us in good stead; for now that skin friction has suddenly taken the foremost place in the

search for still greater speed, we find ourselves already in possession of much useful information about it, although there is still a long way to go before we shall understand its action completely. It is to the consideration of what we already know about skin friction that we must now turn.

A real fluid, such as air, cannot slip over a solid surface; the layers in immediate contact with the surface having no appreciable motion over it. This, of course, is in direct contrast to the ideal fluid of the mathematicians, which is assumed to slip with perfect ease. When one examines the flow of air close to a solid surface, one finds that the velocity parallel to the surface increases very rapidly from zero at the surface to the full velocity of the main stream at a point not far from the surface. The thin sheet of fluid in which this rapid change occurs is called the *boundary layer*. When the flow within this boundary layer is smooth, in the sense that sheets of fluid slip over one another without mixing—like the cards of a pack which is thrown down on a table—we say that the boundary layer is *laminar*, and it is found that when a body, such as a wing, has a smooth surface and a rounded leading edge the boundary layer is smooth—or laminar—for some distance along the surface back from the leading edge. Sooner or later, however, at some point behind the leading edge, this laminar condition breaks down and the flow within the boundary layer becomes *turbulent*, so that the separate sheets of air no longer slip as a whole over one another, but are thoroughly mixed together by the formation of little eddies and erratic movements of small portions of air to and from the surface. Anyone who has looked down over the side of a ship in motion will have seen the effect of this turbulence extending, on a large ship, for a foot or more from the side.

The distance from the leading edge of the wing or the bow of a ship at which the flow within the boundary layer passes from the smooth to the turbulent form is controlled by a number of factors such as the speed of the main flow, the shape and roughness of the solid surface and the turbulence, if any, already in the fluid before it reaches the wing. Speaking roughly, the greater the speed, the greater the roughness, or the greater the initial turbulence of the fluid, the sooner does the transition take place, and although we have a great deal of experimental evidence on the matter, we have, as yet, no means of calculating the distance from the leading edge at which the transition will occur, or even of placing any theoretical limit upon this distance if the surface were perfectly smooth and the main stream perfectly steady.

Experiments made in wind tunnels suggest that at speeds now in contemplation for civil aircraft—say 200 miles per hour—the transition to turbulent flow would be expected to occur within a few inches from the leading edge of the wings and front of the body, so that almost the whole of the surface of the wings and body would be covered by a turbulent boundary layer. But unfortunately there are no large high-speed tunnels yet in existence in which the air stream is as free from turbulence as the open air through which aeroplanes fly; consequently it is to experiments on actual aeroplanes in flight that we must look for a final reliable estimate on this matter. There is as yet very little evidence of this kind available, but the necessary work is in hand.

The practical importance of discovering how far back it is possible to coax the boundary layer to remain smooth will be appreciated from the fact that the skin-friction force exerted by the smooth layer on a high-speed aeroplane would be about one-eighth that of the turbulent layer, so that anything which would increase the area covered by the smooth layer would have a powerful effect in raising the ultimate limit of speed. Assuming, however, for the moment, that it will not be feasible in the near future to retain the smooth form of the boundary layer over more than a small portion of the total exposed surface of an aeroplane, we have to consider the magnitude of skin-friction applied by the turbulent layer.

We have already a considerable knowledge of the skin-friction forces on thin smooth flat plates advancing edgewise into air or water, and we know that on such a plate, as large as the wings of a large aeroplane, the mean skin-friction resistance applied by the turbulent boundary at a speed of 200 miles per hour would be about one-third of a pound per square foot of exposed surface. But, in order to obtain this low figure the exposed surfaces would have to be very smooth. Recent work by Profs. Prandtl and von Kármán has suggested that roughness corresponding to small grains of sand larger than one-thousandth of an inch in diameter, thickly spread over the surface, would appreciably influence the results. Grains, for example, of the order one-hundredth of an inch in diameter would, it is estimated, raise the friction by as much as sixty per cent.

These estimates, it is true, were based only upon experiments made in long pipes with roughened surfaces, and the results were applied to flat pieces of finite length, after elaborate calculations based on unverified assumptions, but, for my part, I believe that the estimates will be found to be substantially correct when checked by direct

measurement on wings of various roughnesses. Such experimental checks should shortly become available from experiments in the compressed air tunnel at the National Physical Laboratory, and from some experiments which we are making at Cambridge to find the resistance of parts of the wings of actual aeroplanes in flight.

As to how far the skin friction on the curved surfaces of a wing or an aeroplane will be the same as that on a flat surface, we are still very much in the dark. The curvature of the wing causes the pressure to change from point to point on its surface, and these pressure changes, or gradients as they are called, influence the flow in the boundary layer and the intensity of the friction applied by it. They also appear to influence the point of transition from smooth to turbulent flow, in the sense that the flow seems more likely to become turbulent when pressure is increasing in the direction of flow. It has long been known that a too rapid pressure rise in the direction of flow reverses the flow in the boundary layer, and is the cause of the separation of flow from the surface of unstreamline bodies ; and it now seems that pressure gradients, much smaller than are necessary to cause separation, may still adversely affect speed by encouraging the boundary layer to take on the turbulent form with its inevitably increased resistance. It may be that the impossibility of avoiding such rising pressure gradients over some parts of the surface of an aeroplane will place a final bar upon efforts to extend the laminar boundary layer over the whole exposed surface, but it is as yet too early to make any definite prediction on this question.

We are now in a position to take stock of the situation in respect of the attainment of high speeds by the civil transport aeroplanes of the near future. The most efficient aeroplanes of the present day have travelled a long way towards perfect streamlining, and achieve cruising speeds of a little less than two hundred miles per hour. It has been estimated that if perfect streamlining were to reduce their head resistance to that of a smooth flat plate of the same exposed area with turbulent boundary layer, they would travel some 20 per cent faster than at present on the same power. Hence there is some improvement, though not much, still to be achieved by perfect streamlining.

Now, however, that skin friction has been promoted from the minor role which it played in the pre-streamline epoch to the principal part which it will henceforth play amongst the factors which limit speed, it is no longer accurate enough to assume that it can be represented by the turbulent layer skin friction on a flat plate, and a great vista of research is opened up, of which the object will be to determine accurately the skin friction on the actual curved surfaces of the aeroplane, and to reduce it so far as possible towards the figure appropriate to the laminar boundary layer. Complete success along these lines might result in a further eightfold reduction of direct head resistance, which might correspond to a nearly twofold increase of speed with the same power. One cannot say yet what part, if any, of this great reduction will ever be achieved, for the difficulties in the way of extending the laminar layer appreciably may be very great, and they may prove to be insurmountable. One can only note the reward to be gained if success were complete, and observe that to achieve a relatively small fraction of this reward would be worth a very great effort.

An alternative to the reduction of head resistance would be an increase of power for weight, and no one can predict what new developments of the power units may occur. But to increase speed greatly by this method alone is a difficult matter, for even if the power were to be doubled, by giving to civil aeroplanes powers comparable to those given to-day to war aeroplanes, speed would be increased only by some 25–30 per cent. Personally, I do not look for much increase along these lines in the near future.

There is one other foreseeable way of evading the restrictions on speed, which is much discussed at present, but which has not yet been exploited. This is to fly very high, using totally enclosed aeroplanes within which pressure and temperature can be maintained at a comfortable level for the occupants. By this means, the direct resistance to motion might be decreased almost indefinitely, at the expense of some increase in what I have called the track-laying power, which, as I have shown, places no final limit on speed. Many very difficult practical problems must be overcome before much can be made of this method, and it is too early to give any estimate of the increases in economical speed which might result from this line of attack. Possibly the ultimate limiting factor here will be the difficulty of cooling the engine at these high altitudes.

For my own part, I feel reasonably confident that stratospheric flying, as this high flying is called, with its as yet unpredictable limits to speed, will eventually provide the principal means of long-distance transport over the earth. For I cannot believe that man will fail to take advantage of the arrangement, so conveniently provided by Nature, whereby the air is thick where he has to land and take off, and thin a little way above, where he can travel at high speed with small resistance and without inconveniencing those who remain on the ground.

Surface Chemistry

THE immense progress that has been made in unravelling the details of surface phenomena, since the fifty years old generalisation of J. J. Thomson and Willard Gibbs that the energy conditions at surfaces may profoundly modify not only the concentrations, but also the chemical equilibria at surfaces, were well surveyed on September 6 in a vigorous and crowded discussion held by Section B (Chemistry) at the Norwich meeting of the British Association. The principal speakers were Profs. H. Freundlich, E. Waldschmidt-Leitz, E. C. C. Baly and E. K. Rideal, and Drs. N. K. Adam, A. H. Hughes and J. H. Schulman. Many of the outstanding points in the behaviour of molecules at the principal types of surfaces which occur in systems of actual or potential biological importance were touched upon in more or less detail.

With the simplest kinds of surface film, the unimolecular films at water-air surfaces, the structure is now so fully known that the size, shape, mechanical properties, orientation and motion of the molecules can be discerned in much detail. The links, also, with structural organic chemistry have been made secure by establishing the truth of Langmuir's generalisations that the surface films behave just as would be expected of a layer of floating objects having all the properties of the molecular models of the organic chemist, and that the field of force of the surface is simply the aggregate of the chemical forces round the surfaces of the individual molecules. Fatty compounds and sterols may have any of a large number of different types of film; the molecules may stand upright, or lie flat, or oscillate though various positions, always, however, keeping the water-attracting end to the water. Proteins and the higher carbohydrates lie flat if there is sufficient space on the surface; they may tilt a little if compressed, but never stand upright. With these simple films every stage of compactness is found, from the dilute gaseous films which have the molecules lying flat and swimming about individually in the surface, to the solid condensed films where they are upright, close packed, and interlocked so as to form a two-dimensional polycrystalline structure.

Unimolecular films may, or may not, be actually present as membranes in living cells; but that their properties are of fundamental importance for cell behaviour is already clear. It is possible to imitate, quite closely, on synthetic unimolecular films of substances present in red blood corpuscles, the phenomenon of hæmolysis. Hæmolytic agents introduced into the underlying water cause a great increase in surface pressure, penetrating into the natural film so as to force the molecules apart and cause it to expand, destroying its natural cohesion. Some such penetration and expansion of the membrane round a corpuscle must occur during hæmolysis. Probably agglutination is essentially due to the penetration of substances into the film, the molecules of which orientate themselves so as to render the outer surface more hydrophobic; the attraction of the cell surface for water is thus diminished and the cells tend to clump together.

There is, as yet, no proof that the intrinsic reactivity of molecules is altered merely by adsorption at a *liquid* surface, but nevertheless the surface may greatly affect the chemical equilibrium and the velocity of chemical reaction, through two factors. First, the actual concentration of the molecular species is usually very much altered through adsorption; secondly, the accessibility of the reacting portions of the molecules may be affected by the particular orientation in the surface. For example, the oxidation of unimolecular films of unsaturated fatty acids which have a double bond in the middle of the hydrocarbon chains is much accelerated if sufficient space is allowed on the surface for the chains to lie nearly flat, so that the double bonds can easily come into contact with the oxidising agent in the underlying water; the oxidation is retarded if the film is squeezed so as to push the chains more upright and the double bonds away from the water. Electrolytic dissociation, also, is often affected by adsorption at the simplest kind of surfaces, a phenomenon which may cause indicators to play unpleasant tricks in solutions of colloidal substances. All such phenomena are, however, only effects of the changes in the environment of the reacting groups in the adsorbed molecules, caused by their crowding and special orientation at the surfaces. A *liquid* surface seems incompetent to impose on adsorbed molecules the strains necessary to activate them, and catalyse the variety of reactions which are caused by enzymes and many solid surfaces. But certain colloidal supports can certainly do this.

Enzymes consist essentially of colloidal protein particles, on a part of the surface of which there is a grouping of atoms which has specific adsorptive and activating properties. Substances in the surrounding liquid must both be adsorbed on this

active patch and be activated when there; there must be a highly specific relation between the structure of the active patch and the substrate adsorbed from solution for both these processes to occur. These surface patches do not appear to constitute any great part of the mass of the colloidal particle, for many pure enzymes activating very different reactions are so similar in general composition that ordinary chemical analysis cannot distinguish between them. The enzyme may thus be regarded as a colloidal carrier having a specific local surface structure. The nature of the carrier is of importance, though it is secondary to the nature of the surface grouping; if the carrier is changed the catalytic efficiency of the enzyme may, or may not, be changed. The complex phenomena of activation of enzymes are often due to the combination of two types of particle; and among the most important activators are the sulphydryl grouping and the iron-containing part of hæmoglobin.

The discussion gave a good idea of the progress made by the new science of the molecular anatomy of surfaces; it is well started and cannot fail to develop rapidly and increase in interest and in usefulness to the biologist, and perhaps ultimately also to the practising physician.

N. K. ADAM.

Migrations of Animals

A COMPREHENSIVE discussion which covered the movements of most of the migratory groups of animals occupied the morning of September 10 at Section D (Zoology) of the British Association at Norwich and brought together much recent information about migration and theories concerning it.

The discussion was opened by Prof. James Ritchie, of the University of Aberdeen, who dealt with the migrations of mammals and directed attention to two problems—the cause or causes of migration and the way in which migratory routes were determined. He described briefly the well-known large-scale movements of such as the lemmings in Scandinavia, the brown rats which invaded Europe from the Caspian region in 1727, the grey squirrels and martens in North America before 1866. These, due to lack of food following undue multiplication, were casual, rather sporadic, one-way movements—overflow movements and not migration proper, and they aimed at no definite goal. True migrations, regular seasonal goings and comings or two-way movements, are of two types, differing in degree rather than essence. The local migration, shown by the red deer of Scottish hills or the Wapiti deer of the Yellowstone Park in the United States, was a movement from summer feeding grounds at high altitudes to a winter range in the shelter of the valleys. Its primary urge was food.

The great seasonal migrations, impressive in extent as well as in the mass of animals taking part in them, were formerly represented by the movements of the wild horses of the steppes of Asia, of the countless antelopes of Africa, the bison, reindeer and musk-oxen of America. They were determined mainly by scarcity of food, though other 'hungers' for water or for salt, also induced regular migrations; and their route often followed regular tracks or roads surveyed and made by far distant ancestors after trial and error towards a definite goal. Road-making is characteristic of the daily activities of mammals, and migratory tracks formed a heritable property handed down from generation to generation. Such an explanation of migration avoids the need of invoking any special migratory instinct or special sense of direction.

Dr. N. A. Mackintosh described the migrations of whales from the antarctic region where they are most abundant during the summer, gorging upon the crustacean *Euphausia superba*. In winter they move northwards to temperate waters for the breeding season, and although actual migrations have not been often traced, the circumstantial evidence is strong. For example, in the antarctic, whales fatten enormously as the summer advances, and then off South Africa whales very fat in body and yet with empty stomachs are found, clearly immigrants from the antarctic feeding grounds. Again in winter off the African coast whales bearing fresh scars were found, but when whales were caught in the antarctic the scars were healed —they had been contracted in warmer waters during the northern migration. How the migrating whales are guided on their movements is not clear: except in coastal waters landmarks seem to be out of the question, but perhaps the temperature of the water controls the movements, since the regular presence of whales seen from the *Discovery* in the antarctic shows that they frequent tongues of warm water and are obviously sensitive to temperature.

Recent discoveries regarding the migrations of birds were described by Dr. A. Landsborough Thomson, who pointed out that the old idea of narrow migration routes along coast-lines and river-valleys had been abandoned in favour of the

idea of migratory movements upon a broad front. The extraordinary complexity and variety of migration in different species, sometimes closely related, were illustrated by a series of well-chosen examples, some selected from the recently investigated movements of birds confined to tropical areas; but it was pointed out that overriding all the complexities a regularity of time and place and route characterises migratory movements as a whole. The outstanding problem still to be solved is that of route-finding, and although there are many indications that vision plays an important part (for example, fog is one of the serious disturbances of a migration) yet the orientation of a migration journey must still be looked upon as something of a mystery.

Some interesting results of marking experiments were described by Dr. E. S. Russell in discussing the migrations of fishes, where knowledge of migration is of great economic importance since the movements of concentrated shoals of food fishes regulate the fisheries. In fish-marking experiments, hundreds of thousands of individuals have been marked and a high return of 30–40 per cent gave a clear indication of the major movements, which was supplemented by the analysis of fishery statistics. Generally speaking, the migrations of fishes consist of three movements—of mature fish to the spawning grounds, generally upstream, a dispersion after spawning, generally downstream, and local seasonal migrations such as that of the tunny into the North Sea in autumn. Dr. Russell illustrated these facts by describing in detail recent observations upon the movements of cod, plaice and salmon.

The series of general papers on migration was concluded by an account of the migrations of insects by Dr. C. B. Williams. In this case, migration does not necessarily include a return flight, though in the last five years evidence has accumulated that some Lepidoptera do make a return journey. Migration is widespread in the insect world, many instances being known from the groups of Lepidoptera, locusts, dragon-flies and beetles. One of the most remarkable cases is that of the American monarch butterfly which spends the summer so far north as Alaska and winters in the southern States and Mexico, returning to a state of semi-hibernation in the same groups of trees year after year, although one or two generations have passed since the former occupants had traversed the migration route. The extraordinary movements of the world-wide painted lady butterfly were described, and it was shown that insect migration takes place in definite directions, and is independent of the direction of the wind. The understanding of insect migration is complicated by the short life of insects which makes impossible any learning of the route from direct ancestral experience.

The migration symposium was a popular feature of the Section's discussions, and was attended by a very large audience.

Character and Causes of New Stars

AT the British Association meeting in Norwich, a discussion on new stars was opened in Section A (Physics) on September 10 by the Astronomer Royal (Dr. H. Spencer Jones), and other papers were contributed by Mr. J. P. M. Prentice, Prof. F. J. M. Stratton, Prof. W. H. McCrea, Mr. E. G. Williams, and Dr. A. B. Wyse and Mr. R. H. Stoy. The following is a summary of some of the chief points which emerged.

A new star may be defined for practical purposes as a star the apparent brightness of which increases within a few days by some five magnitudes or more. The first well-authenticated historical record of a nova is of that observed in 1572 by Tycho Brahe, and since then novæ have been looked for and observed with increasing zeal. This may be illustrated by the fact that, since 1901, forty-two galactic novæ have been recorded, and of these seven have been near enough and discovered soon enough for detailed spectroscopic study. These seven include Nova Herculis 1934, discovered by Prentice, through whose promptitude in communicating the fact a spectrum was obtained by Martin at Greenwich within one hour after discovery.

The 'light-curve' of a nova in general shows a steep rise to its principal maximum, followed at first by a steep fall, and then by a more gradual fading, with small fluctuations, to something very near the pre-outburst magnitude. The case of Nova Herculis, however, showed novel features in the way of many comparable maxima, extending over some months, before the steep drop occurred. The intrinsic surface brightness, as judged by the effective temperature, does not in general change much before the principal maximum, and hence the increase in total brightness must be attributed to an increase in the radiating surface. In a typical case, the radius of the star, as defined by its photosphere, must increase about a hundredfold. In the later stages, however, the effective temperature does increase very considerably, so

that the final radius when the star has returned to approximately its initial total brightness may be perhaps 1/25 of the pre-outburst radius. The net consequence of the outburst being thus a contraction of the whole star, it results in the liberation of a vast amount of gravitational energy of which some, at any rate, must supply the energy for the increased radiation during the eruption.

The variation of brightness of a nova is accompanied by a highly complex sequence of changes in its spectrum. Before the principal maximum the spectrum is not greatly different from one of the ordinary spectral types. The absorption lines, which are then its chief feature, show by their displacement towards the violet the general swelling up of the star already deduced from its increase in brightness. After maximum, multiple absorptions appear with large violet displacements, and each in general bordered on the redward side by bands of emission the mean position of which coincides in each case with the undisplaced position of the corresponding spectral line. These features can be explained by supposing that one or more shells of gas are thrown off from the star and accelerated away from it, probably under forces due to radiation pressure. This has in some cases been confirmed by the fact that, after enough time has elapsed for these shells to attain sufficient size, it has been possible to observe them directly as a growing nebulosity around the parent star. There is also spectroscopic evidence in some cases for the ejection of matter in irregular jets rather than, or as well as, in symmetrical shells. In addition, turbulence appears to develop in the ejected matter.

In the further spectral development the absorptions gradually disappear, giving way to a bright line spectrum in which a number of 'forbidden' lines of oxygen [O I] and [O III], and iron [Fe II], make their appearance. The whole sequence is consistent with what may be expected from the increase of temperature of the parent star and the decrease in density of the expanding envelope. The final spectrum is of Wolf-Rayet type, the structure of the lines suggesting the continued emission of gas. It seems probable that the nova is then approaching a white dwarf state.

Photometric measurements of novæ spectra have recently yielded valuable information confirming both the hypothesis of the expanding gaseous shells and also the high colour temperature attained by the nuclear star in the later stages. Further, the photometry of the absorption lines due to interstellar Ca^+ yields an estimate of the distance of the nova. This method gave for Nova Herculis a distance of 1,200 light-years, which shows that at maximum it was 30,000 times as bright as the sun.

The estimated rate of appearance of novæ in the Milky Way agrees well with Hubble's estimates of the number appearing in the Andromeda nebula, which may be regarded as a comparable system. If this rate is assumed uniform, it shows that in about 3×10^9 years every star would become a nova. This is approximately equal to the lowest estimate of the age of the stars, so it seems likely that such a flare up may in fact happen to every star. The most plausible explanation of the phenomenon is provided by E. A. Milne's theory, according to which instability sets in at a certain epoch in the evolution of a star, causing it to pass over into a 'collapsed' configuration, with the liberation of a large amount of gravitational energy. The same theory shows that, if the star is originally rotating, the collapse may cause it to split into two components, which need not then remain collapsed, thus suggesting an origin for double stars.

It is extremely doubtful whether novæ constitute a homogeneous class of objects. Whereas the total brightness in most cases increases ten- or a hundred-thousand fold, it seems that the nova of 1572 underwent an increase of about 16 million fold. Similar cases have been observed in other galaxies. So the isolation of a class of *super*-novæ is indicated, and it has been suggested by Baade and Zwicky that their outbursts provide the source of cosmic radiation. Again the behaviour of stars like RS Ophiuchi and T Pyxidis makes it seem probable that there is also a class of *recurrent* novæ.

W. H. McC.

Geological Relations of Early Man in East Anglia

THE discussion on this topic, held on September 5 at the Norwich meeting of the British Association, has revealed a far greater measure of agreement between geologists and archæologists than has emerged during any previous review of the subject. The division of the East Anglian glacial deposits into four distinct groups has provided a framework into which most of the archæological finds appear to fit quite naturally; it is thus not surprising that discussion should now centre around the more obvious of the remaining doubts and difficulties.

The first of these concerns the authenticity and cultural position of the various sub-Crag industries.

The best pieces from this horizon are now fairly generally accepted as human, both by geologists and archæologists; but some enthusiasts among the latter are apt to spoil their case by the obstinate advocacy of a great deal of poorer material which, convincingly human as it may be to their experienced eyes, can scarcely be expected to impress geologists who lack their special knowledge of these early industries. In any event, it is becoming increasingly clear that no general agreement can ever be obtained as to the exact position of the beginning of the Stone Age; but it seems justifiable to record a majority of informed opinion in favour of the human origin of some at least of the flints found below the East Anglian Crags. Some archæologists claim to recognise a Chellian facies in these cultures; but there are not many who would support their reference to the Chellian as usually recognised at present.

The next difficulty is the determination of the geological position of the true Chellian culture. This is largely due to the occurrence of a depositional hiatus between the first ('North Sea') and second ('Great Eastern') glaciations. Further, with the exception of one implement found by Mr. J. E. Sainty in the North Sea Drift, all the known Chellian specimens from East Anglia are heavily abraded, and are clearly much older than the deposits in which they are now found. Mr. Sainty's implement appears to indicate a pre-glacial date for the industry, and this accords well with its occurrence at Abbeville in association with a Cromerian fauna; but in that case it was probably of very long duration, since the Acheulian industry does not appear in England until after the second glaciation. It is to be hoped that further study of the deposits belonging to the first interglacial period, such as occur in the Midlands, will provide some help towards the solution of this problem.

The Acheulian of East Anglia appears to belong entirely to the second interglacial period. The only possible exceptions are provided by a few pieces found by Mr. J. Reid Moir in the so-called 'Upper Chalky Boulder Clay' and associated gravels in the Ipswich district. But as this 'Upper' boulder clay is no more than a surface modification of the great sheet of Chalky Boulder Clay which covers most of Norfolk, Suffolk and Essex and is known to underlie the Acheulian brickearths at Hoxne and at Derby Road, Ipswich, it seems reasonable to regard Mr. Moir's specimens as having reached their position from the surface; this could be explained either by later solifluxion or by descent into frost cracks.

It is now generally accepted that the flake industries of Clacton and High Lodge were broadly contemporaneous with the Acheulian, although the exact parallelism of their various stages has not yet been fully worked out.

The deposits of the third ('Little Eastern') glaciation frequently contain Acheulian and Clactonian implements. They have long been known from Gresham on the Cromer Ridge and from the gravels of the Breckland; Mr. Sainty has recently been finding them at several new localities in West Norfolk.

The archæological history of the third interglacial period is a matter of doubt. Apart from a few scattered Upper Palæolithic finds, the prevalent culture belonging to this interval is a curiously mixed assemblage suggestive of a degenerate Levalloisian or even Clactonian industry with traces of Upper Palæolithic influence. As it occurs largely on surface sites of no stratigraphical value it has been somewhat summarily referred to the Neolithic by many archæologists, in spite of the fact that real Neolithic forms and technique are wanting. Mr. Reid Moir's 'Lower Floor' at Bolton's pit, Ipswich, represents this industry; it is also known from Morston in Norfolk and is probably found on many surface sites in the Breckland.

It is to be hoped that archæologists will make a detailed study of this industry, which has certain well-marked peculiarities of technique and is probably peculiar to Great Britain.

The mesolithic industries are never found in glacial deposits even where the fourth glacial period is represented, and they are therefore considered as entirely post-glacial.

Such is the state of our knowledge of these problems as revealed by the recent discussion. Other points raised were the questions of nomenclature, of the position of the Pliocene-Pleistocene boundary and of the possibility of making a detailed chronological Drift map for the assistance of the archæologists.

Prof. P. G. H. Boswell suggests that the suffix '-ian' should be uniformly adopted for all the Palæolithic industries; this would appear to be logical and to follow the standard practice of British geology. The question of the Plio-Pleistocene boundary would eventually have to be settled by international agreement, but meanwhile there would seem to be a strong case for following the palæontologists, who place it at the horizon of the appearance of *Equus*, *Bos* and *Elephas*; that is to say, below the Red Crag of East Anglia.

The possibility of a detailed Drift map would seem to be small until the Pleistocene sequence has been correlated over the whole country; archæologists will therefore have to rest content with the ever-increasing number of criteria provided by the geologists for the differentiation of the various Drift deposits. J. D. SOLOMON.

Lubrication

AT a joint meeting of the Sections G (Engineering) and A (Physics) of the British Association in Norwich, on September 9, several problems in connexion with lubrication were discussed.

The field of lubrication may be regarded from several points of view. In the first place the design of bearings of different types for various species of mechanism presents a number of novel mathematical and engineering difficulties several of which, especially in reference to the thrust bearing, were considered at the meeting.

A suitably designed bearing will make the best use of the lubricating medium, which must be automatically entrained, rejected and replenished by the action of the bearing itself.

Whilst it is satisfactory to note that there has been during the last few years a very marked improvement in the design of bearings and in the methods and materials of their manufacture, it is equally clear that progress is not nearly so rapid in the second field of inquiry, namely what constitutes a good lubricating oil. This problem becomes daily more acute, for, as emphasised by more than one speaker, the modern development of the aero engine necessitates efficient lubrication at increasingly higher temperatures.

It has, of course, long been recognised that bearings design and materials, load, speed and temperature are all important factors which influence the frictional loss when any one lubricant is employed. It is very satisfactory to note that a number of testing machines are now available in which these factors can be varied independently.

It is unlikely that testing machines of different types will place a series of lubricants in identical orders of merit. If it be accepted that the duties of a well-designed bearing is to replenish oil at least as rapidly as it is consumed, it is necessary to inquire into the factors which cause consumption of oil and the nature of the products of destruction. Presumably a bearing may fail or record a high frictional loss, not on account of undue oil consumption but through insufficient entrainment of fresh oil, a fault which may be due either to the mechanical design of the bearing or to the physical properties, especially the fluidity, of the oil itself, or to a combination of both these factors. It would appear that some time must elapse before testing machines are devised which permit us to segregate the intrinsic characteristics of lubricating oils such as life or stability, oiliness and other more well-defined properties without reference to the type of bearing.

In respect to the mode of operation of the lubricant in boundary lubrication, the thesis of the late Sir William Hardy comprised two separate hypotheses. First, that a lubricant had to contain a substance capable of forming a monolayer on the metal anchoring itself by means of a polar group to the bearing surface and presenting to the liquid interface a long non-polar chain. Secondly, that above this monolayer a relatively thick orientated film was formed, termed diachysis by Hardy, a phenomenon which apparently bears a resemblance to the so-called cybotactic properties of certain liquids.

Both industrial and research experience have proved the correctness of Hardy's first assumption, but the weight of experimental evidence is now definitely against Hardy's hypothesis of a diachytic chain as possessing any real existence in a warm and moving bearing containing a fluid lubricant.

At the same time it is evident that the simple addition of say a long chain acid to a normal paraffin is not sufficient to produce the ideal lubricant although the orientated monolayer is formed under these conditions.

Two important factors have to be taken into consideration: first, the life of a monolayer is not indefinite, indeed, there is now evidence to show that one single passage of a slide over a surface lubricated with a monolayer is sufficient to destroy the lubricating properties of the layer. It follows that the bulk of the oil must be so constituted that it can act as a reserve for the rapid supply of fresh molecules to form the monolayer.

The rise of surface temperature, which may be surprisingly high, up to the melting point of the metal, has two important consequences: first, the distribution of the lubricating semi-polar molecules between the surface and the bulk phase, if controlled by a Boltzmann distribution, will be unfavourably affected, and secondly substances prone to thermal or oxidative chemical reactions will be destroyed. Whilst little is known about the rates of such disarrangements and chemical reactions in actual bearings, electron diffraction photographs reveal the non-uniform nature of the surface, and it is not surprising that attempts are being made to improve lubricants by the addition of polymeric and micelle-forming substances which are stable towards oxygen, less readily desorbed and renewed when destroyed at rates greatly superior to the long chain fatty acids.

E. K. R.

Obituary

Dr. Peter Giles

WE regret to record the death of Dr. Peter Giles, Master of Emmanuel College, Cambridge, and distinguished philologist, which took place in Cambridge on September 17 at the age of seventy-four years.

Peter Giles was born at Strichen, Aberdeenshire, on October 20, 1860, and after graduating at the University of Aberdeen, he went up to Cambridge as a scholar of Gonville and Caius in 1882. He was placed in the first class in both parts of the Classical Tripos and in the second class in history; and he won a number of University prizes. He was elected a fellow of Caius in 1887; but in 1890 he migrated to Emmanuel, and in 1891 was appointed reader in comparative philology in succession to Dr. Peile. In 1911 he became Master of his college. Throughout his academic career he fulfilled the many duties in College and University to which he was called, with conspicuous success by the exercise of qualities which won him the affectionate respect of all with whom he came into contact.

Giles's influence in the study of comparative philology began to be felt when the exuberant enthusiasm aroused by Max Müller's early teaching was waning under the cold breath of criticism. His "Short Manual of Comparative Philology for Classical Students" (1895) introduced a new and saner method to British scholarship. Nevertheless it was only very slowly that philology came to be regarded as anything but a highly specialised and circumscribed study, which could contribute little to the analysis of the broader aspects of cultural development which absorbed the attention of archæologist and ethnologist. Here again it was the influence of Giles and his writings, and more especially his contributions to Hastings's "Encyclopædia of Religion and Ethics" and the Cambridge Histories, that did much to restore a truer sense of balance and proportion. The brilliance and sanity of his discussion of the Aryan problem, as well as the convergence of his views towards lines which were being traced by archæological research, once more directed attention to a body of evidence which, with due recognition of its limitations, students of the origins of European culture could no longer afford to neglect.

Mr. T. H. Riches

THE death of Mr. Thomas Henry Riches, on September 19, at the age of seventy years, will be much regretted by his many scientific friends. As an undergraduate at Caius College, he was much interested in zoology, and after taking his degree in 1888, he devoted some time at Plymouth to the study of the Nemerteans. Here he published an account of the local forms, and collected material for elucidating the embryology of *Cephalothrix*; though before this work could be brought to satisfy his critical and rather fastidious mind, the burden of wealth was thrust upon him and he had perforce to turn his attention elsewhere.

Throughout life, however, Riches kept in close touch with zoological developments, and when experimental heredity became prominent he embarked on breeding research with rabbits—continuing it for a number of years. Though here again he published nothing in his own name, he discovered many interesting facts which, through the medium of others, were ultimately incorporated into our standard knowledge of the genetics of this animal.

More recently, Riches undertook an investigation into the genetics of the form of achondroplasia which appears as 'bull-dog calves' in Dexter-Kerry cattle, and of the analogous monstrosities in the Scandinavian Telemark breed, and these experiments were in progress at the time of his death. Art claimed his interest as well as science, and probably many readers of NATURE will remember him as a generous benefactor to the Fitzwilliam Museum and other good causes.

THE death has occurred in Berlin of Dr. Lydia Rabinowitch-Kempner at the age of sixty-three years. She was born at Kovno in Lithuania and studied medicine at Zurich and Berne and then in Philadelphia, where she taught in the Women's Medical College during the winter, and in the summer frequently carried out researches in Koch's laboratory in Berlin. Her first scientific work to attract attention was on the presence of non-pathogenic acid-fast bacilli in 60 per cent of the specimens of butter examined in Berlin. She then devoted her attention to tuberculosis and published articles on avian tuberculosis, spontaneous tuberculosis in domestic animals, hereditary transmission of tuberculosis in birds, etc. She also carried out researches on trypanosomiasis with Koch and on plague with Walter Kempner, another of Koch's assistants, whom she married. In 1912 she was the first woman to obtain the title of professor for scientific work. For some years prior to the anti-Semitic campaign in Germany she was editor of the *Zeitschrift für Tuberkulose* and director of the Bacteriological Department of the Moabit Hospital, Berlin.

WE regret to announce the following deaths:

Prof. Max Cremer, emeritus professor of physiology in the University of Berlin, and formerly head of the Physiological Institute of the Veterinary College, Berlin, aged seventy years.

Prof. A. Guntz, professor of applied chemistry in the University of Algiers, and *correspondant* of the Academy of Sciences, Paris.

News and Views

Dr. Arnold Berliner and *Die Naturwissenschaften*

WE much regret to learn that on August 13 Dr. Arnold Berliner was removed from the editorship of *Die Naturwissenschaften*, obviously in consequence of non-Aryan policy. This well-known scientific weekly, which in its aims and features has much in common with NATURE, was founded twenty-three years ago by Dr. Berliner, who has been the editor ever since and has devoted his whole activities to the journal, which has a high standard and under his guidance has become the recognised organ for expounding to German scientific readers subjects of interest and importance. A personal friend of Dr. Berliner writes: "When addressing the editor on his seventieth birthday in the inaugurating page of a festival issue, Albert Einstein said, 'His journal cannot be imagined as absent from the scientific life of our time'. Extremely small, indeed, is the number of journals which fulfil the task of uniting by a strong bond the separated and highly specialised work of the leading students in the various domains of science. The editor's important rôle and his active contribution to the progress of research, in conducting a periodical of this kind, are of a different order of magnitude from that of an ordinary 'Fachzeitschrift'. In order to cope with his task, he is obliged to exert very definite leadership on a body of prominent men, everyone of whom is liable to see things distorted from the point of view marked by his own interests and achievements. The editor is the one who has to survey the broad stream of scientific development, to select which subject-matters are suitable for presenting to his readers, to have intimate knowledge of the abilities (scientific and otherwise) of his contributors and, finally, after deciding upon the best writer upon a particular subject, to coax him into fulfilling towards his colleagues a duty of which sometimes neither he nor they are aware and to which the man himself often feels little inclination. It would need a large volume (and, maybe, more than one) to embody only those first-class essays which would never have been written, had it not been for the impossibility of resisting our dear and esteemed friend's gentle command".

Centenary of Darwin's visit to the Galapagos Archipelago

ON September 16, 1835, in the course of the voyage of the *Beagle*, a call was made at the islands of the Galapagos archipelago in the Pacific. This visit was one of the most momentous incidents in the life of Charles Darwin, who was on board the ship as naturalist, for the observations which he was enabled to make gave that orientation to his thoughts which ultimately led him to formulate his theory of the evolution of species. He records in his diary: "The natural history of these islands is eminently curious and well deserves attention. Most of the organic productions are aboriginal creations, found nowhere else; there is even a difference between the inhabitants of the different islands; yet all show a marked relationship with those of America, though separated from that continent by an open space of ocean between 500 and 600 miles in width. The archipelago is a little world within itself, or rather a satellite attached to America, whence it has derived a few stray colonists and has received the general character of its indigenous productions. Considering the small size of these islands, we feel the more astonished at the number of their aboriginal beings, and at their confined range. Seeing every height crowned with its crater, and the boundaries of most of the lava-streams still distinct, we are led to believe that within a period geologically recent the unbroken ocean was here spread out. Hence both in space and time, we seem to be brought somewhat near to that great fact—that mystery of mysteries—the first appearance of new beings on this earth."

Galapagos Exhibition at the Natural History Museum

To commemorate Darwin's visit to the Galapagos archipelago, a selection of the more characteristic forms of the reptiles and the birds, which were the elements of the fauna that especially claimed Darwin's attention, is exhibited in the Reptile Gallery of the British Museum (Natural History), South Kensington; some of the specimens, indeed, were collected by Darwin himself. Series of mocking-thrushes (*Nesomimus*) and finches (*Geospiza*) are arranged to show the variations in structure and distribution which are described in the "Journal of Researches" and which have puzzled ornithologists ever since. The characteristic giant tortoises, and marine and terrestrial iguanas are also shown, and attention is directed to the destruction of the fauna during the past century and to the imminent danger of its disappearance owing to the introduction and uncontrolled spread of predatory domestic animals.

Darwin and H.M.S. *Beagle*

THE president of the British Association, Prof. W. W. Watts, has received from H.M.S. *Beagle* a cablegram, recalling the centenary of Darwin's landing from the former *Beagle* on the Galapagos Islands. This important event in the history of biological science was duly noticed at the recent meeting of the Association in Norwich. (See NATURE of September 14, p. 426.) The cable pays tribute to "our most distinguished passenger", and adds that "the present *Beagle* salutes the British Association, the trustees of science". An appreciative acknowledgment, wishing good luck to the present *Beagle*, has been returned.

Bicentenary of James Keir, F.R.S.

ON September 29 occurs the bicentenary of the birth of James Keir, an able chemist and the friend

of Erasmus Darwin, Boulton, Watt, Priestley and Davy. The youngest of a family of eighteen and born in Stirlingshire, after attending the High School and University of Edinburgh he entered the Army and afterwards served for several years in the West Indies. Resigning his commission in 1768, he settled in the Midlands, became connected with various industrial enterprises and devoted himself to chemistry and geology. He was in turn a glass manufacturer at Stourbridge, an assistant to Boulton and Watt at Soho and the founder, with Alexander Blair, of a soap and alkali works. With Blair, too, in 1794 he opened the Tividale Colliery. In 1776 he translated Macquer's "Dictionary of Chemistry" and in 1777 published a treatise on elastic fluids or gases. He also contributed chemical papers to the Royal Society, and in 1785 was elected a fellow. A chemical dictionary of his own, of which he published the first part in 1789, he discontinued on his becoming convinced of the weakness of the phlogiston theory. For many years he lived at West Bromwich, where he died October 11, 1820, at the age of eighty-five years.

Adam Politzer, 1835–1920

ADAM POLITZER, one of the principal founders of otology, was born at Alberti in Hungary on October 1, 1835. He studied medicine in Vienna under Skoda, Rokitansky, Oppolzer and C. Ludwig, and qualified in 1859. In 1861 he was appointed lecturer in otology, and during the following years held a number of appointments in the University of Vienna connected with his speciality, being elected professor of otology in 1895 and director of the otological clinic in 1898. In addition to a textbook on otology first published in 1878, which ran through many editions and was translated into English in 1883 and 1902, he was the author of numerous articles on the anatomy and physiology of the ear and its diseases, especially suppurative otitis media and polypi. In 1864 he helped to found the *Archiv für Ohrenheilkunde*, and in 1895 the Austrian Otological Society. The Vienna ear clinic possesses a rich collection of anatomical and pathological specimens of the ear prepared by him. His name is attached to a method of inflation of the middle ear through the Eustachian tube by a pear-shaped rubber bag introduced through the nostril. He died in his eighty-fifth year on August 10, 1920.

Louis Ranvier, 1835–1922

LOUIS ANTOINE RANVIER, the eminent French histologist, was born at Lyons on October 2, 1835. His medical education took place in Paris, where he qualified in 1865, and two years later became Claude Bernard's assistant at the Collège de France. In 1875 he was appointed to the chair of general anatomy in the Paris faculty of medicine, and held this appointment for more than thirty years. In 1886 he was elected a member of the Paris Academy of Medicine and in the following year a member of the Academy of Sciences. He also became a member of numerous foreign academies and learned societies. His principal works are the "Manuel d'histologie pratique", written in collaboration with Cornil (1869–76) and his "Traité technique d'histologie" (1875–82). He made numerous contributions to the proceedings of the Société de Biologie and Academy of Sciences, and published a large number of papers in the *Journal de l'Anatomie et de la Physiologie*, *Archives de Physiologie*, *Journal de Micrographie*, etc. The term 'Ranvier's nodes', which is familiar to every biological student, has been given to the annular constrictions of the neurilemma associated with discontinuity of the medullary sheath of the nerve fibre. Ranvier died on March 22, 1922, in his eighty-seventh year, at Vendranges, Loire, where he had been living in retirement for some years.

'Legislative Anthropology'

DR. ARTHUR MACDONALD, of Washington, D.C., and formerly fellow of Johns Hopkins University, is well known for his advocacy of the claims of 'legislative anthropology', that is, study of the legislative, political, psychological, sociological and physical status of members of a legislature or parliament. He holds that as chosen servants of the people, members of the United States Legislature, for example, coming from all sections, are truly representative, and afford a good opportunity of establishing the anthropological status of the country. He goes further and argues that a similar study in other countries would afford a basis for comparison as between nations. At present, his opportunities are confined to material from the United States. He has made a study of certain physical characters of eighty-nine members of Congress, of which the results were published in the *Congressional Record* of the Seventy-second Congress, First Session, under date May 11, 1932. The figures then given established some interesting correlations, especially when studied in their geographical distribution according to States. Dr. Macdonald has now instituted some interesting comparisons between these members of Congress and a number of the insane, although he admits that the latter have no distinctive physical character. The number of individuals measured in this category was 360. They were chosen for their intelligence and included ex-army and naval officers and professional men. The majority, however, had no more than common school education, and for the most part had practised trades. The following are some of the measurements: *Congress*—length of head, 196 mm.; breadth of head, 156 mm.; height of head, 139 mm. *Insane*—length of head, 190 mm.; breadth of head, 151 mm.; height of head, 139 mm. It is to be noted, however, that while stature and weight in members of Congress are respectively 177 cm. and 183 lb., in the insane they are 170 cm. and 150 lb. Obviously the figures need further analysis before any significant conclusion can emerge.

An Education Film—"Northern Lights"

THE sound film entitled "Northern Lights" seen recently at a private view at the offices of the Western Electric Co. at Bush House, Aldwych, London, W.C.2,

is the film record of the expedition that set sail from the Port of London in July, 1930, in the late Sir Ernest Shackleton's old ship the *Quest*, under the leadership of Gino Watkins, to explore the possibilities of an air route between England and Central Canada. It is now available under the Western Electric Company's "All-in" Hiring Service, under which films, equipment and operators can be hired under one inclusive hiring fee, and is the latest addition to a series of educational films specially suitable for schools, that includes "Climbing Mount Everest" and "With Byrd at the South Pole". The photography is of a high standard, particularly in view of the trying conditions under which much of it was done. Particularly impressive was the record of a blizzard at the Expedition's base on the east coast of Greenland, views of the driving clouds of snow on the mountains being followed by others showing the subsequent gale in the fiord, which averaged 80 miles-an-hour and reached 120 miles-an-hour in gusts. Through the spindrift could be seen the floes of ice being hurried out towards the open sea, and the whole effect, combined with the accompanying sound record of the shrieking of the wind, was extremely impressive. There were glimpses also of the Eskimos and their kayaks, and of the members of the crew learning to use these vessels for the purpose of hunting seals, and finally of actual seal hunts. A good idea is given of the laborious sledge journeys in melting snow, and on ice slopes, and of the part played by the dogs—huskies from the west coast of Greenland. The educational value of the film is considerable, and it should prove very entertaining, as well as instructive, at schools.

Extension of Messrs. Negretti and Zambra's Works

MESSRS. NEGRETTI AND ZAMBRA, whose high reputation for scientific and industrial instruments is well known, have just completed a fourth extension of their works consisting mainly of a double floor building of approximately 10,500 square feet. The first floor comprises a new electrical thermometer department and experimental department with an extension for aircraft instruments. In the assembly of certain electrical thermometers it is very desirable to have a dust-free atmosphere, and very special care has been taken to ensure cleanliness in this department. For this purpose, an air-conditioning plant is installed which supplies the shop with filtered air, and if required, heated air free from dust and dirt. The air is led through a comparatively large duct along the roof and into the shop through adjustable nozzles placed at intervals along one side of the building. As the whole building is practically air-tight, a series of exhaust fans are provided in the window frames on the opposite side of the shop for exhausting the air. This ensures a flow of pure air across the shop with no entry of impure air. Consideration has also been given to the flooring to avoid dust, and this is a wood block floor of Austrian oak. The test room is separated from the main shop by partitions, and this is likewise kept dust-free. The equipment of the test room includes standard potentiometer, millivoltmeters, thermometer-testing baths, etc. The expansion has resulted also in an enlargement of the existing machine shop and a further expansion for the manufacture of mercury-in-steel thermometers.

Archæological Investigations in Shansi, China

RECENT excavation and an archæological reconnaissance in the province of Shansi, China, by Mr. C. W. Bishop, associate curator of the Freer Art Gallery, Smithsonian Institution, Washington, D.C., have made possible a remarkably detailed reconstruction of the late neolithic culture of north China. In an interim summary report of the results issued by the Smithsonian Institution, it is stated that the human skeletal remains discovered indicate that in the main the prehistoric population is identical with that which occupies the country to-day. A village site, which was excavated, was found to consist of beehive-shaped pit-dwellings, about ten feet deep, which were entered from the top. The present inhabitants of the district live in dwellings excavated in the cliff face, sometimes in two or more tiers, the entrance being in front. The prehistoric villagers were settled agriculturists, with the dog and pig as their only domesticated animals. They cultivated their fields with a stone hoe. They wore woven clothes, as well as using bark-cloth, and must therefore have been acquainted with some plant affording fibre for textiles. They also wore skins and furs; and they wove baskets and mats. Their implements were of stone, bone, deer antler and, no doubt, wood. Adzes, axes and knives, both rectangular and semi-lunar, often perforated, were found, as well as arrow points of stone, bone and shell. Although immense quantities of potsherds were found, there were few complete vessels. It is interesting to note that the pottery falls into two classes, of which the earlier was hand-made (coiled) and the later, falling at the end of the stone age, was painted. The hand-made pottery was decorated with impressed, incised or applied ornament; the painted pottery shows a buff or red-brown ground, on which geometric designs were painted in black, red or white. There is evidence of human sacrifice, and possibly of ritual cannibalism. This culture precedes the Chinese Bronze Age, which is known to have begun some centuries before 1500 B.C.

Bureau of American Ethnology

FOLLOWING the precedent of last year, the fifty-first annual report of the Bureau of American Ethnology is reduced in size and does not include the "Accompanying Papers" describing the field-work of the staff, which for so long have made this publication year by year one of the most important contributions of the United States to the literature of anthropology. The fifty-first report covers the operations of the staff of the Bureau in office and field up to June 1934. In the interests of economy, field-work was much curtailed, and for the most part took the form of supervision of the archæological investigations which have been put in hand in the States of

Tennessee, Georgia, Florida and California by Federal authority as part of the measures under the Civil Works Administration for the relief of unemployment. Of these investigations, the most extensive were in California, where extensive excavations at the Buena Vista Lake, Kern County, under Dr. H. D. Strong and Mr. W. M. Walker revealed evidence of extensive occupation and some six hundred interments. Nearly 5,000 artefacts and specimens were obtained, as well as information which throws a flood of light on the prehistoric inhabitants of the great southern valley of California and their ethnic affiliations. Mr. J. N. B. Hewitt's study of the Iroquois continues to reveal new and interesting details in the organisation of the Confederacy of the Five Nations, and this year promises to be of exceptional importance to the student of Indian tribal relations. Incidentally, the report shows another side of recent political 'scandals', alleged in criticisms of unemployment relief, by a reference to the specially qualified unemployed who were engaged to translate or transcribe material from the Bureau's archives hitherto inaccessible to study, or in danger of perishing.

British Hardwoods

IN a paper entitled "Our British Grown Hardwood Trees", read before the Forestry Sub-section of Section K (Botany) at the meeting of the British Association in Norwich on September 5, Mr. Alexander L. Howard traced the history of the forests, their denudation and afforestation work in Britain from the time of Henry II down to the present day. After reference to the disappearance of forests in other parts of the world and the resulting troubles caused thereby, Mr. Howard turned his attention to the afforestation work proceeding in Great Britain. What we want, he says, is the largest number of trees of both softwoods and hardwoods to be planted in the shortest possible time at the least possible cost. On the latter head there will be no disagreement; on the former, a certain section of opinion in Great Britain holds that, with the present high taxation, the whole of the burden of this afforestation work, the benefits of which can only be realised by future generations, should not fall upon the present one. After an analysis of the present position of the Forestry Commission and its expenditure, Mr. Howard advocates the formation of a regular Government Department "modelled on the lines of the best-known systems at present in existence". Mr. Howard—and many will agree with him—is insistent on the importance of increasing the areas of hardwood trees in Britain.

Plant Diseases in Egypt

THE Technical and Scientific Service of the Ministry of Agriculture for Egypt has recently issued a most valuable Bulletin on "Egyptian Plant Diseases: a Summary of Research and Control" (Bull. No. 146, Govt. Press, Bulâq, Cairo. Price P.T. 5. 1935). Mr. G. Howard Jones, director of the Ministry's Mycological Section, has written the text, which is a discussion of Egypt's position in relation to plant diseases, with a list of those which have occurred up to the present. Desert on three sides, and the sea on the fourth, render that country a somewhat isolated region, whilst the flooding of the Nile and the regularity of the seasons are further peculiarities. Rigid plant quarantine is one of the most effective methods of controlling fungus diseases in such an area. Research work has been directed to the investigation of individual diseases, the selection and testing of resistant host plants, the effects of differing level of the soil water table, and the progressive simplification of disease control. The last-mentioned question is of vital importance, not only in Egypt, but wherever busy farmers have to control disease in their crops. Seed disinfection with dusts is preferable to hot water treatment or to the use of liquid fungicides. The preparation of Bordeaux mixture is a very complicated process, so much simpler spray fluids are being developed. Eight reproductions of illustrated posters, with descriptions in the native language, are included in the Bulletin. One feels that Mr. Howard Jones and his colleagues really understand the situation in Egypt, and are doing their best to control the more serious diseases. The greater part of the publication is devoted to the list of diseases of crop plants, arranged according to their hosts, whose names appear in alphabetical order.

International Agriculture

"THE WORLD AGRICULTURAL SITUATION IN 1933-4", published by the International Institute of Agriculture, Rome (25 liras), forms the fifth of the series of "Economic Commentaries" on the "International Yearbook of Agricultural Statistics". The information is presented in a slightly different form from that in preceding volumes. The first part deals with world agriculture, its conditions and trends, and describes the market conditions of the chief agricultural products such as cereals, sugar, tea, coffee, wine, tobacco, textile materials and live-stock, while the second part is concerned with the agricultural policy and conditions in each of thirty different countries. A modification of the arrangement in the previous issues has been made and now information of every kind concerning each country has been grouped together in a single article. The development in Government intervention on behalf of agriculture has necessitated considerable extension of this part of the publication and has also led to the omission of the section devoted to the action taken by voluntary organisations, since this has inevitably become of increasingly smaller importance.

Shelterbelts and Windbreaks

IN Great Britain, shelterbelts are usually constructed as a protection against wind alone. In countries possessing arid areas of large expanse, like India and Mesopotamia, they are sometimes usefully employed against driven sand and dust. In these countries, the hot weather is usually accompanied by a daily wind rising with the sun and attaining its maximum about 1 p.m. and then gradually dying away. In some cases, the wind is so strong that it

carries small pebbles with it. It is not sufficient merely to plant grass to arrest the travelling sand dunes. The best way seems to be to plant suitable trees. In a paper by Dr. R. M. Gorrie published in the *Empire Forestry Journal* (**14**, 1; 1935) a scheme for enlarging farming shelterbelts so that they extend from the Canadian border down to Texas is described. Thousands of farmers have accepted aid from the Department of Agriculture, and the belts that have been constructed have greatly increased the comfort in which they live. In the arid Middle West, fruit growing becomes a possibility only when a shelterbelt is made. Dr. Gorrie says that the American scheme consists in multiplying the existing small windbreaks until about 2,500 square miles of forest has been planted. The layout of the belts is determined by the worst wind, and a width of about 150 feet is usually employed. As a means of relieving unemployment the scheme proved useful. In the same number of the *Journal* Mr. C. J. W. Pitt-Schenkel describes windbreaks in Tanganyika territory. A series of windbreaks are being planted across part of the country to check erosion and to protect the grass from being dried up rapidly by the prevailing wind.

Radium Deposits in North-West Canada

IN *Sands, Clays and Minerals* of June 1935, published by the Westmoor Laboratory, Chatteris, England, Dr. H. S. Spence, of the Canadian Department of Mines, gives an authoritative and well-illustrated account of the discovery, occurrence and exploitation of the pitchblende deposits found by Gilbert Labine in 1930 on the eastern shore of Great Bear Lake. Work to date has demonstrated the existence of extremely rich ore in three veins. Three months' operation of the Eldorado Company's mill showed that the raw material is of exceptionally high grade, the best being equivalent to a radium content of one gram per 6½ tons. Occurrences of native silver add to the value of the deposits, some of the ore assaying up to 9,000 oz. of silver per ton. In veins 1 and 3 and in part of vein 2 the pitchblende was originally deposited in botryoidal crusts which were later brecciated and re-cemented by quartz. In the other part of vein 2 the gangue material is not silica, but carbonates of manganese, iron and lime, together with barytes. It is this section of vein 2 which is characterised by native silver, in flakes and leaves occurring in both pitchblende and gangue.

OTHER discoveries of pitchblende have been made in this region; one immediately to the east of La Bine Point; another ten miles to the south-east; and another at Beaverlodge Lake, a hundred miles to the south. The last of these discoveries was made by smell! Indians had noticed a peculiar smell when camping at La Bine Point. In the winter of 1934 when the ground was covered with snow, they showed a prospector a spot on Beaverlodge Lake where they had noticed a similar smell. The snow was cleared and a pitchblende vein was disclosed beneath. An official town site has now been established at Cameron Bay, just south of La Bine Point. The Eldorado Company's radium refinery is at Port Hope, fifty miles east of Toronto, 4,000 miles from the mines. Up to June 1934, the plant had isolated 5½ grams of radium from 58 tons of pitchblende, together with 35,000 pounds of uranium compounds and 30,000 oz. of silver.

Reduction in Price of German Books and Periodicals

As a result of comments upon the excessive cost of German periodicals recently made in Great Britain and the United States, German publishers, two years ago, reduced their prices by 20 per cent. (See article by Dr. W. Bonser, Librarian of the University of Birmingham, NATURE of July 1, 1933, p. 34, and again of October 7, 1933, p. 540.) Unfortunately this reduction was at once counterbalanced by the fall in the value of the pound sterling. The German publishers are, however, making a further reduction, so that now the benefit will be appreciable. We are informed that: "From September 9th, 1935, there will be a discount of 25 per cent on the published prices of all new books originating from and published in Germany, on music and on all graphical instructive material, on subscriptions to periodicals, provided they were not charged before that date". The reductions will make a great difference to all university and society libraries; for example, the physiological *Berichte*, formerly costing 6 vols. at RM. 68 will now be at RM. 51—a saving of about £8 a year.

Recent Earthquakes

WE have received from Kew Observatory a notice of a violent earthquake recorded there at 14 h. 16 min. on September 11. The epicentre is estimated to have been in about lat. 43° N., long. 146° E., or about thirty miles off the south-east coast of the northern island of Hokkaido. This point is about thirty miles to the north of the epicentre of the destructive earthquake of April 25, 1843, after which seawaves 16 ft. high swept over the coast, and about eighty miles north-north-east of that of the less destructive earthquake of March 22, 1894, which was followed by seawaves about 5 ft. high on the coast of Hokkaido and 10 ft. high at Kamaisi on the east coast of Japan. A very violent earthquake was recorded at the Observatory at 2 h. 8 min. 13 sec. G.M.T., on September 20. The epicentre is estimated to have been 7,500 miles away, probably under the Pacific Ocean near the Mariamme Islands.

String-Figures

KATHLEEN HADDON (Mrs. O. H. T. Rishbeth), unquestionably our foremost expert in the study of the string-figure, has published a selection of these ingenious diversions for the use of beginners ("String Games for Beginners", Heffer and Sons, Cambridge. 6*d*. net). Twenty-four figures given here will serve as an introduction to their endless variety, and afford those previously uninstructed some idea of their wide distribution in various parts of the world. Mrs. Rishbeth has drawn on her own material collected in New Guinea and Australia, on figures brought back by Dr. A. C. Haddon from the Torres Straits, and

on material from various tribes of the Indians of North America. Instructions are reduced to their simplest terms, and a brief introduction sets out the significance of the string-figure, and explains why it is of interest to science as an indication of the life and thought of the people among whom each type of game occurs. Mrs. Rishbeth has considerately supplied a suitable piece of string which is attached to the book for the use of the reader.

Health of the Navy during 1933

THE health of the Navy during 1933 is detailed by the Medical Director-General, Surgeon Vice-Admiral R. W. B. Hall, in the Statistical Report of the Health of the Navy for the Year 1933 (London: H.M. Stationery Office. 2*s*. 6*d*. net). In a total force of 83,125, the number of cases of disease and injury was 41,852, a ratio of 503·48 per thousand, an increase of 40·53 in comparison with the five years' average and an increase of 31·80 in relation to 1932. The increase appears to be mainly due to an increase in the incidence of influenza and tonsillitis. Malaria, venereal diseases, tuberculosis and injuries, all show a decrease. The total number invalided also shows a decrease. Details are given respecting cases of interest and the pathological tests and surgical technique employed.

The Natural History Museum and Broadcasts to Schools

THE trustees of the British Museum have arranged for special talks and exhibits at the Natural History Museum in connexion with the biology course being broadcast to schools on Wednesdays, from September 25 until December 11, from 2.30 to 2.50 p.m. Within the limits of the accommodation, schools may attend at the Museum and listen to the broadcast talk in the board room, and immediately afterwards visit the appropriate specimens in the galleries under the guidance of the museum guide lecturer. For the benefit of schools which prefer to receive the broadcasts in their own classrooms, a special tour of the specimens by the guide lecturer will be available every Thursday at 2.30 p.m. For schools which may find it more convenient to attend at the museum only once or twice a term, more extensive tours may be arranged if particulars of what is required be addressed to the director. Arrangements also may be made with the director for schools unable to attend on Thursday afternoon to have the same lecture tour at some other time.

Announcements

THE ninety-fourth session of the School of the Pharmaceutical Society of Great Britain will begin on October 2, when Sir Frederick Gowland Hopkins will deliver the inaugural sessional address, at 3 p.m.

PROF. ALBERT SZENT-GYÖRGYI, who discovered vitamin C in capsicum, has succeeded Prof. Szeuky as director of the First Chemical Institute and professor of organic chemistry at Szeged.

THE twenty-fourth Congress of the Italian Society for the Advancement of Science will be held in Palermo on October 12–18 under the presidency of His Excellency the Honourable Di Marzio, rector of the University.

THE German General Medical Congress for Psychotherapy will be held at Breslau on October 3–6, when the subject for discussion will be psychical treatment in relation to psychiatry, internal medicine and education. Further information can be obtained from Dr. Hausdörfer, Psychiatrische Klinik, Breslau.

THE Fishery Institute of the University of Königsberg, directed by Prof. Willen, has organised a vacation course from October 9 until October 16 at the sea fishery station at Neukuhren, Samland, consisting of lectures, practical work and excursions, to illustrate the hydrography and biology of the Baltic. Further information can be obtained from Fischerei Institut, Universität, Königsberg.

PARTICULARS of lectures, courses and classes arranged by the Warburg Institute and dealing with the survival of classical elements in European history of religion, social life, fine arts, science and literature have recently been issued. All lectures, courses and classes are open to the public, and admission is free. Further information can be obtained from the Secretary, Warburg Institute, 3 Thames House, Millbank, London, S.W.1.

THE sixth Turkish Medical Congress will be held at Angora at the end of October under the patronage of the President of the Turkish Republic and the presidency of General Ismet Inöniü, the president of Council and Prof. Refik Saydan, the Minister of Health and Social Assistance. The subjects for discussion will be rheumatism and alcoholism and drug addiction in Turkey. An exhibition of pharmaceutical products and medical instruments will be held during the Congress. Further information can be obtained from the general secretary, Prof. Fahrettin Kerim, 15 Boulevard D'Angora, Stamboul, Turkey.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A temporary demonstrator in botany in the University of Leeds—The Registrar (Sept. 30).

A lecturer in engineering in the Plymouth and Devonport Technical College—The Secretary for Education, Coburg Street, Plymouth (Oct. 5).

An assistant pomologist at the John Innes Horticultural Institution, 21 Mostyn Road, S.W.19—The Secretary (Oct. 7).

A chemical pathologist in the Department of Clinical Investigations and Research in the Manchester Royal Infirmary—The Director (Oct. 11).

A curator of the Zanzibar Museum—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, London, S.W.1 (Oct. 15).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 517.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Dielectric Constant of Ionised Air

IN recent years, a large number of experiments have been carried out on the dielectric constant of ionised air with the object of verifying the Eccles-Larmor theory, which demands that the dielectric constant of an ionised gas should be less than unity. Study of the literature on the subject reveals, however, that most of the investigations are of a qualitative nature, and further that the experimental results obtained are often of an anomalous type, the recorded dielectric constant being frequently equal to, or greater than, instead of less than, unity.

The present note briefly describes and gives the results of an experimental investigation by which a quantitative agreement with the prediction of the theory is secured, and an insight is gained into the origin of the anomalous results by previous workers.

The principle of the experiment is the same as that employed for measuring the dielectric constant of a medium by the Lecher wire system. The air, contained in a glass tube (diameter 3 cm., length 75 cm.) and ionised by electric discharge, is placed between the Lecher wires, with the length of the tube parallel to the wires. The Lecher system is excited by an ultra-short wave valve oscillator. The wave-length in the ionised air is measured on the wires in the usual way by noting the positions of the bridge for resonance, and is compared with that measured in non-ionised air. Keeping the discharge current constant, the frequency f of the valve oscillator is varied and a series of wave-length measurements made. A graph plotted between K, the apparent value of the dielectric constant calculated from the change in wave-length, and $1/f^2$ gives a curve of the form ABC shown in Fig. 1.

Remembering that $K = 1 - 4\pi Ne^2/m(p^2 + \nu^2)$, conductivity of ionised air $g = Ne^2\nu/m(p^2 + \nu^2)$, and that resonance measurements give us wave-length of propagation $\lambda = 2\pi/\beta$, where β is wave-length constant (a function of g), e and m are electronic charge and mass respectively, ν is collisional frequency, $p = 2\pi f$ and N is electronic concentration, we can interpret the curve as follows.

From A to B the curve is nearly a straight line. In this portion ν^2 is negligible compared with p^2, and λ is very nearly equal to $2\pi/p\sqrt{CL}$ since g is small (C and L being capacity and inductance per unit length of the Lecher wires). K therefore varies inversely as f^2.

From B onward the curve takes an upward turn. The dispersion here is apparently anomalous; K seems to increase with $1/f^2$. This anomaly is due to the fact that from B the value of ν^2 becomes comparable with p^2, and the effect on λ of the leakage between the wires due to conductivity of the ionised air begins to be appreciable. β has a tendency to increase and λ, as measured from the positions of resonance, decreases. K calculated from these values of λ decreases as $1/f^2$ increases.

In an actual experiment from the results of which the curve is drawn, the following values were obtained:

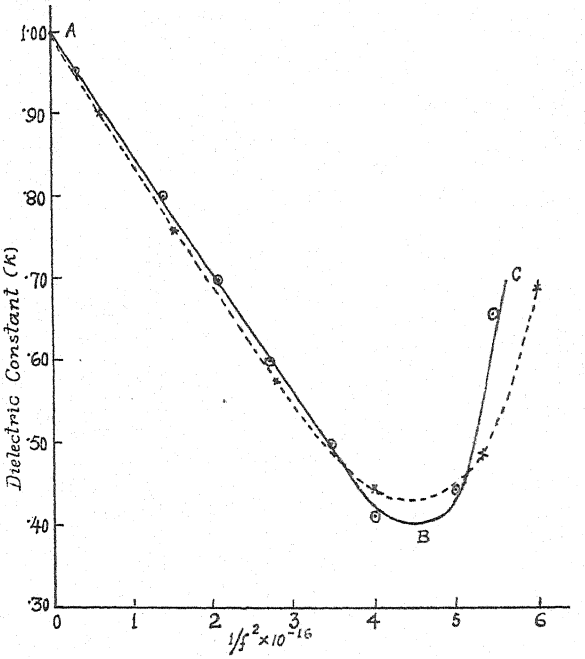

FIG. 1. Variation of dielectric constant of ionised air with $1/f^2$, where f is the wave frequency.

$N = 1{\cdot}87 \times 10^7$ electrons per c.c. (calculated from observations when $p \gg \nu$; $\nu = 1{\cdot}15 \times 10^8$ (calculated from the temperature of the electrons and the pressure in the discharge tube; temperature determined experimentally by Langmuir's probe method); $f = 37{\cdot}9 \times 10^8$ to $4{\cdot}0 \times 10^8$. A curve plotted between apparent K and $1/f^2$ as calculated from these data is shown in dotted lines in Fig. 1. It will be seen that the agreement between the experimental and the theoretical curve is as good as may be expected.

The curves thus furnish on one hand a quantitative verification of the Eccles-Larmor theory of the decrease of the dielectric constant of ionised air below unity, and also explain how, due to the conductivity acquired by the air, an anomalous increase of the dielectric constant comes to be recorded.

It may be mentioned here that in the usual experimental procedure adopted hitherto, the object was to detect, in a more or less qualitative way, the sense of the change in the capacity of a parallel plate

condenser when the air between the plates contained in a glass tube is ionised by electric discharge. The parallel plates themselves are placed either inside or outside the discharge tube. Various explanations of the observed anomaly in these experiments have been proposed. These may be classified as: (*a*) existence of quasi-elastically bound electrons (Gutton), (*b*) formation of ionic sheaths on the condenser plates when these are placed inside the discharge (Appleton), and (*c*) conductivity (Pedersen, Appleton, etc.). The Gutton effect has been examined by Appleton and shown to be a distinct phenomenon not connected with the anomaly. Sheath formation has little or no effect, as is shown by the fact that curves similar to *ABC* have been obtained by us with the Lecher wires running inside the discharge tube. It therefore seems certain that the conductivity acquired by the ionised air is the true cause of the anomalous results obtained.

A detailed account of the investigation will shortly be published elsewhere.

Photodissociation of Nitrous Oxide

THE action of light on nitrous oxide has been studied by several workers in recent years. It was found by Wulf and Melvin[1] that N_2O, when irradiated by light of λ 2350 A., broke up into NO and N. Later on, Dutta[2] studied the absorption spectrum, and found that light was continuously cut off from a long wave-length limit λ 2750 A., and showed that the energy equivalent of this wave-length accounts for the dissociation of N_2O into NO and N, both in the normal states. I extended this work[3] in the Schumann region, and two more continuous absorptions were found beginning from the long wave-length limits λ 1850 A. and λ 1580 A., separated by a region of transparency; it was shown that these further absorptions are responsible for raising N, one of the products of dissociation, to the metastable states ^2D and ^2P respectively. In short, the absorption of light by N_2O takes place in the following steps.

$$N_2O + h\nu_{2750} = NO\ (^2\Pi_{\text{normal}}) + N(^4S) \quad . \quad . \quad . \quad (1)$$
$$N_2O + h\nu_{1850} = NO\ (^2\Pi_{\text{normal}}) + N(^2D) \quad . \quad . \quad . \quad (2)$$
$$N_2O + h\nu_{1580} = NO\ (^2\Pi_{\text{normal}}) + N(^2P) \quad . \quad . \quad . \quad (3)$$

The values of $h\nu_{2750}-h\nu_{1850}$ and $h\nu_{1850}-h\nu_{1580}$ could be compared with the values of $^4S - {}^2D$ and $^2D - {}^2P$ respectively obtained from the classification of atomic spectrum of N.

Recently, Henry[4] has remeasured the absorption spectrum of nitrous oxide at different temperatures and obtained the long wave limit of continuous absorption as λ 2140 $\pm$ 130 A. at absolute zero, by extrapolation. This value is quite different from that obtained by the earlier investigators. Henry assumed a process of dissociation like the following:

$$N_2O\ (^1\Sigma) + h\nu_{2140} = NO\ (^2\Pi) + N(^2D) \quad . \quad . \quad . \quad (4)$$

This photochemical equation is claimed to explain not only the diamagnetism of N_2O (giving a $^1\Sigma$ state), but also the calculated value of the heat of dissociation of N_2, which is $6{\cdot}9 \pm 0{\cdot}2$ volts, is also found to agree with the latest value, 7·34 volts, given by Herzberg and Sponer[5]. It might be pointed out that opinions as regards the diamagnetic nature of N_2O differ, and at present there is no recent work to settle the point. There are several other points which may be put forward against the process (4) given by Henry.

The value $D_{N_2} = 6{\cdot}9 \pm 0{\cdot}2$ volts is decidedly lower than the present accepted value, 7·34 volts, given by Herzberg and Sponer. Herzberg and others have pointed out in several places that the energy of dissociation calculated from continuous absorption spectra always comes out higher than the true value. I have shown in a recent paper[6] that whenever there is a long tail of continuous absorption as in N_2O in the present case, the potential energy curve representing the interaction of the dissociated products will be very steep. Hence the absorption of light indicated by a vertical Franck-Condon transition from the ground-level will give a fairly high value of the heat of dissociation. The value of D_{N_2} calculated from such observations will be correspondingly higher than the true value, and not lower as obtained by Henry.

If the first long-wave limit of continuous absorption accounts for the dissociation of nitrous oxide into NO($^2\Pi$) and N(^2D) as indicated by (4), the two subsequent absorptions in the Schumann region beginning from λ 1850 A. and λ 1580 A. respectively, given by equations (2) and (3), will have to be interpreted in a different manner, probably in the following way only:

$$N_2O + h\nu_{1850} = NO\ (^2\Pi_{\text{normal}}) + N(^2P) \quad . \quad . \quad . \quad (5)$$
$$N_2O + h\nu_{1580} = NO\ (^2\Pi_{\text{excited}}) + N(^4S) \quad . \quad . \quad . \quad (6)$$

From (4) and (5) we get:

$$h\nu_{1850}-h\nu_{2140} = 0{\cdot}86 \text{ volts nearly}$$

and from (4) and (6):

$$h\nu_{1580}-h\nu_{2140} = 2{\cdot}06 \text{ volts nearly.}$$

These values are expected to give respectively the values of $^2D - {}^2P$ (= 1·19 volts) of N, and $^2\Pi_{\text{normal}} - {}^2\Pi_{\text{excited}}$ (= 5·61 volts) of NO approximately. The great lack of agreement here seems to throw doubt on Henry's suggestion regarding the photochemical dissociation of nitrous oxide in the quartz region. It cannot adequately account for the subsequent absorptions found by me in the Schumann region.

Further light is thrown on the problem from observations on the fluorescent spectrum of N_2O. I found[7] that when N_2O is irradiated by light having the short-wave limit at λ 1200 A., the β-bands of NO comes out in fluorescence. It was shown that in N_2O the production of the β-bands of NO can be accounted for in the following way only:

By absorption—

$$N_2O + h\nu_1 = NO(^2\Pi_{\text{normal}}) + N_{\text{normal}} \quad . \quad . \quad . \quad (7)$$
$$N_2O + h\nu_2 = NO(^2\Pi_{\text{excited}}) + N_{\text{normal}} \quad . \quad . \quad . \quad (8)$$

By fluorescence—

$$NO(^2\Pi_{\text{excited}}) \xrightarrow{\beta\text{-bands}} NO(^2\Pi_{\text{normal}}).$$

The excitation energy of the β-bands[8] is 128·8 k.cal., so that $h\nu_2 - h\nu_1 = 128{\cdot}8$ k.cal. If, according to Henry, $h\nu_1$ corresponds to λ 2140 A., we get $h\nu_2 = 262{\cdot}4$ k.cal corresponding nearly to λ 1090 A.

nearly. Consequently, light of wave-length greater than λ 1090 A. should not be able to excite the β-bands. Excitation can be brought about by λ 1200 A.; if $h\nu_1$ is taken to be in the neighbourhood of λ 2750 A. (Dutta), $h\nu_2$ comes out as near λ 1250 A.

Electron Diffraction by Vitreous Silica Powder

I HAVE succeeded in showing recently that the comparatively coarse particles of any powder are suitable for structure investigation by means of electron diffraction[1]. For this purpose a mineral or other substance is ground carefully in a small mortar. The powder obtained is placed in a sedimentation air tube like that described by Gonell[2]. When blowing the slow jet of air through the heap of powder disposed at the bottom of this sedimentation tube, only the coarsest particles will return, while the minute ones will move with the air blast to the top of the tube where there is a big receiver. By placing there a suitable holder, for example, a loop of wire with a thin celluloid film for the transmission method, or a support for the reflection method, one can collect the particles, the sizes of which depend on the speed of the air blast. It is possible also to collect the smallest particles at the bottom of the tube. For this purpose it is necessary to blow the air for a few minutes only until the smoke appears at the top of the tube, and then to wait, in the case of a tube of one metre in length, in general about 10–15 minutes. Then all particles larger than 0·1–1·0 μ in size are precipitated at the bottom of the tube, the remaining being still suspended in the air. To collect the latter on the holder it is sufficient to wait in the case mentioned above about half an hour, after which the process had to be repeated a few times to accumulate a layer of sufficient thickness. It may be noted that the diffraction haloes from the celluloid film disappear completely only when the layer is thick enough. In this way I have obtained sometimes sufficiently clear diffraction patterns from specimens, which were otherwise quite unsuitable for electron diffraction, for example, ignited magnesia, sand, cements and tripolites. Mrs. L. I. Tatarinowa has proposed another method for preparing the specimens by drying on the celluloid film a drop of liquid with a fine suspension of the substance to be studied. This method, which gives sometimes excellent specimens for electron diffraction, has an especial advantage in that it requires only the minutest portion of substance. I have used successfully both these methods.

Here I will confine myself to the case of electron diffraction by vitreous silica glass, which does not give sharp rings when exposed to X-rays. It is of interest that such an amorphous body behaves like a true crystalline aggregate (see Fig. 1). On the best photographic plates, I have succeeded in measuring sometimes up to ten and even more distinct rings, which correspond approximately to the following Bragg spacings d:

Int.	*hkl*	(observed) d	(calculated) d
Weak	—	4·40	—
Very strong	111	4·03	4·04
Strong	002	3·64	3·64
Very strong	022	2·52	2·50
Weak	113	2·17	2·17
,,	222	1·99	2·02
,,	133	1·65	1·62
Fair	224	1·47	1·46
Weak	242	1·42	1·42
Fair	044	1·26	1·25
Very weak	026	1·11	1·14
,, ,,	046	1·01	0·99

(The first extra ring belongs presumably to an adsorbed organic substance from the vacuum grease.) Some of these rings, namely, the most intense ones, have been observed by L. R. Maxwell and V. M. Mosley[3] in their work on electron diffraction by transmission of electrons through thin films of silica glass. In spite of the lack of accuracy of the measurements, I am inclined to think that the above results can only be interpreted as a scattering by tetragonal cristobalite crystallites constituting the vitreous SiO_2. The axial ratio is 1·06; $a = 6·87$; $c = 7·28$. The size of these cristallites, which is probably of the order of 15–20 A., as estimated by J. T. Randall, H. P. Rooksby and B. S. Cooper[4] by measuring the breadth of X-ray diffraction band, is sufficient to give very sharp diffraction rings. The electron wave-lengths in my experiments were about 0·06 A., while these authors, as well as B. E. Warren[5], used an X-ray wave-length of 1·54 A., so that the sharp electron diffraction patterns with many lines are, of course, the consequence of greater resolving power of the electron rays. Hence the method of electron diffraction is applicable to a much larger range of substances than hitherto supposed.

Induced Radioactivity of Nickel and Cobalt

USING nickel as a receiving plate for the recoil of radio-elements produced in the Fermi effect I have found, contrary to the statements of Fermi and his co-workers[1], that this metal acquires a slight activity under neutron bombardment. This effect must be attributed to nickel, because it is exhibited by chemically pure nickel plates and nickel oxide. Further investigations have shown that the induced radioactivity of nickel is composed of two parts, one decaying with a period of about 20 minutes and another with a period of the order of a few hours. The activity of both products is very small: nickel plates of 0·1 mm. thickness exposed for 12 hours to the full neutron radiation of 40 millicuries of radon mixed with beryllium give an initial effect of 1·5 impulses per minute. The long-life activity is enhanced 4–5 times, when neutrons are allowed to pass through water; the short-period product shows no increase in this case. It is therefore probable that the first product is an isotope of nickel. The possible reactions leading to this product are:

$$_{28}Ni^{58} + {}_0n^1 = {}_{28}Ni^{59} \quad . \quad . \quad . \quad (1)$$
$$\text{and} \quad {}_{28}Ni^{62} + {}_0n^1 = {}_{28}Ni^{63} \quad . \quad . \quad . \quad (2).$$

Reaction (2) is more probable since its end product would be the stable isotope 63 of copper. The small relative importance of Ni^{62} in nickel would account for the smallness of the effect observed.

As for the second product of about 20 min. period, I have been led, on the ground of some rules based on a survey of artificial radio-elements, to the following reaction:

$$_{28}Ni^{60} + {}_0n^1 = {}_{27}Co^{60} + {}_1H^1.$$

In order to test this assumption, I have irradiated cobalt in a large vessel containing water. In addition to the known radio-element Mn^{56} of about 2·5 hours period[1] I have found another activity which has a period of about 20 minutes and which does not appear when no hydrogen medium is used. The initial activity due to this product is of the order of 6 impulses per minute. The corresponding reaction must be:

$$_{27}Co^{59} + {}_0n^1 = {}_{27}Co^{60}.$$

Spiral Orbits and the Law of Recession

FROM certain considerations of isotropy, one of us has obtained, in a paper communicated elsewhere for publication, the line-element

$$ds^2 = -e^{\mu}(dr^2 + r^2d\theta^2 + r^2\sin^2\theta d\varphi^2) + e^{\nu}dt^2, \quad . \quad (1)$$

where $\mu = \log(A + Bt + \frac{1}{2}t^2)$ and $\nu = 2\log r$, A and B being arbitrary constants of integration. If $A = B = 0$, the geodesics give a straight line motion according to the law

$$\dot{r}/r = c/t, \quad . \quad . \quad . \quad . \quad (2)$$

where $c = -2$ or $\pm\sqrt{2}$. The two-dimensional motion is given by $\dot{r}/r = D/t$, and $\dot{\varphi} = \sqrt{(2 - D^2)}/t$, . . (3)

so that $r d\varphi/dr = \sqrt{(2 - D^2)}/D$, . . . (4)

which gives an equiangular spiral. If the spiral structure of the nebulæ is due to particles describing equiangular spirals as given by (4), and if the law of recession of the nebulæ themselves is of the form (2), then the line-element (1) seems to be of great interest in the relativistic theory of world-structure.

Density of 100 per cent Heavy Water

THE density of D_2O was firstly estimated by Lewis and Macdonald[1] to be: $d_{25}^{25} = 1{\cdot}1056$. Later Taylor and Selwood[2] found a higher number: $d_{25}^{25} = 1{\cdot}1079$, and this figure has been used by several investigators. However, during the technical progress of concentration at the plant of the Norsk Hydro-Elektrisk Kvælstof A/S at Rjukan, indications were obtained that this figure was too high, and a number of careful pyknometer determinations of the density of 100 per cent D_2O in large quantities were, therefore, conducted.

The results obtained for the normal 100 per cent D_2O product (for which the density of the distilled electrolyte and that resulting from the combustion of hydrogen and oxygen from the cells were identical) were as follows:

$$d_{20}^{20} = 1{\cdot}10711;\ 1{\cdot}10712;\ 1{\cdot}10713;\ 1{\cdot}10714,$$

of which the highest figure ($d_{20}^{20} = 1{\cdot}10714$) must be considered to be the nearest approach to the true value. The pyknometer determinations were correct to 0·000001. The value of the density obtained corresponds to $d_{25}^{25} = 1{\cdot}1074$, that is, actually considerably lower than Taylor and Selwood's figure.

In order to determine the content of heavy oxygen in the water employed, 100 per cent D_2-gas was lead over hot copper oxide containing the normal O^{16}/O^{18}-ratio. The resulting water had a density: $d_{20}^{20} = 1{\cdot}1070$, and consequently the isotopic ratio of the oxygen in the 100 per cent D_2O products does not differ appreciably from the ordinary ratio. Concentration of heavy oxygen during electrolysis of water is, however, actually found to take place under certain conditions[3,4], and the high figure of Taylor and Selwood for the density of heavy water may be due to a higher proportion of heavy oxygen in the samples employed.

On the other hand, the density of 'light water' with a D_2O-content less than 1 : 200000 has also been determined. d_{20}^{20} for this product was found to be $0{\cdot}9999815 \pm 1\,\gamma$.

Follicular (Œstrus) Hormone and Plant Tumours

A FEW years ago I observed that female rats and mice, given subcutaneous injections of a watery suspension of *B. tumefaciens*, or subcutaneous implantations of the crown gall tumours of pelargoniums, appeared to reach sexual maturity before control animals did. Harde[1], Yano[2], Dodds[3], and others, have given experimental proof of the possibility of a carcinogenic sensitisation of animals through administration of sexual—especially the follicular—hormones.

In previous experiments[4] it was clearly shown that the œstrus hormone had marked effects upon certain plants, and it was also observed that, when introduced in toxic doses through a petiolar stump into tomato plants, this hormone manifested its effects upwards along the stem, above the point of introduction.

In the present experiments, a similar introduction of an aqueous solution of a hormone was made into tomato plants, which were afterwards inoculated above and below the petiole with *B. tumefaciens*. Commercial crystalline œstrus hormones ('Glandubolin' of Richter, and 'Hogival' of Chinoin), prepared from urine of pregnant mares, were used; the average total dose absorbed was 434·3 mouse units per plant during the period June 8–21, 1935. In spite of the high dosage, toxic effects were almost negligible in comparison with those seen on tomato plants similarly treated in winter[4].

Thirty-one plants were treated with hormone, and a similar number served as controls; all were inoculated with *B. tumefaciens*, but twenty-one received distilled water, and ten received a deproteinised, hormone-free extract of animal tissue—in all cases via the petioles.

At the first sign of necrosis of the tumours they were cut off and weighed. The average weights of the tumours per plant were as follows:

Treatment	Position of tumours in relation to petiolar stump	
	Above	Below
Œstrus hormone	0·554 gm.	0·303 gm.
Controls:		
Distilled water	0·452 gm.	0·427 gm.
Special extract	0·407 gm.	0·423 gm.

These results indicate that though the weights of the tumours on the control plants were not significantly a function of their position, the mean weight of the uppermost tumours on the plants treated with œstrus hormone was about 80 per cent greater than the mean weight of tumours below the petiole.

The final interpretation of these observations must depend upon further work to decide whether the direction of migration of the hormone in the plant is constant, or whether it is different with physiological and toxic doses.

Effect of Vitamin C (Ascorbic Acid) on the Growth of Plants

THE effect of vitamin C on plants was studied with sterile plant cultures. 40 mgm. of crystalline ascorbic acid was added to the liquid medium. It was found that the dry weight of the treated plants was about 35–75 per cent higher than that of the controls. The differences were greatest during flowering. The treated plants also showed a much higher content of vitamin C, particularly at the early stages. These results are illustrated by the table below. It is pointed out that the observed increase of growth is specifically due to ascorbic acid, and not merely to an addition of organic material to the inorganic medium, since a similar addition of glucose effected no increase in the growth of the plants.

Mycorrhizal Habit in the Genus *Citrus*

IN a communication to NATURE, written when visiting the Citrus Experimental Station, University of California, I directed attention to the mycorrhizal habit in species of *Citrus* used as stocks for orange in Southern California, and to the possible relation of this habit with observed inconsistencies of response to the application of nitrogenous fertilisers[1]. The matter is one of considerable practical interest in view of the prevalent use of such fertilisers and the heavy cost of manuring in Californian orchards.

An investigation followed, the recently published results[2] of which justify the views expressed in my original note. Intensive study of the cytological changes in the roots of plants from experimental plots receiving different manurial treatments leads the authors to emphasise "the importance of the mycorrhizal association as a factor in the metabolism of *Citrus* root cells", and to conclude that: "the relations between the root cell and the endophytic fungus contribute to an understanding of the responses

of the tree to nitrogenous fertilizers, and to the conditions favorable for infection by the endophyte".

Mycorrhizal structure as observed in *Citrus* under cultivation in California is similar to that found in the same species under natural conditions. The remarkably wide geographical distribution of this 'Phycomycete type' of mycorrhizal association, its prevalence in plant species of the most diverse affinities, together with its recorded appearance in certain crop plants, prompts me to urge once again the need for expert diagnosis of root condition in respect to mycorrhizal equipment as an index of soil environment favourable or the reverse, and as a guide to efficient manurial treatments of crops showing regular mycorrhizal associations.

Electrical Conductivity of Copper Oxide Films Showing Interference Colours

THE measurement of the electrical resistance of films of copper oxide on copper showing interference colours of the first order has given results varying from 0·002 to 15 ohms per sq. cm. at 25° C. On massive copper surfaces the temperature coefficient of the resistance is positive and somewhat less than that of metallic copper, while the resistance measured is very small, lending support to the view that the very fine structure of the film is very heterogeneous and minute areas of metal are probably exposed. These areas are too small for the microscope and spectrophotometer to show their presence.

With activated surfaces the electrical resistance is very much higher, and the temperature coefficient is negative, like that of the oxide. Although the surface colour showed striking homogeneity in many cases, shearing and breaking the metal showed a considerable thickness (up to 10^{-3} cm.) of activated film and graded colour sequences through the fracture corresponding to thinner films on the granules as the distance from the surface increased.

Points from Foregoing Letters

THE variation of the dielectric constant of ionised air with wave frequency has been determined by Prof. S. K. Mitra and S. S. Banerjee. Their findings verify the Eccles-Larmor theory, which demands that the dielectric constant of an ionised gas should be less than unity, and shows that owing to the conductivity acquired by the ionised air, an anomalous increase of the dielectric constant is recorded.

Prof. P. K. Sen-Gupta adduces several arguments to substantiate his claim that nitrous oxide gas, N_2O, is broken down into NO and N by ultra-violet light of wave-lengths 2750, 1850 and 1580 A. (in which regions nitrous oxide has absorption bands), and not by wave-length 2140, at absolute zero, as claimed by Henry.

A photograph indicating the electron diffraction pattern obtained with powdered vitreous silica is submitted by N. A. Shishacow. Unlike the photographs obtained with the same material with X-ray of wave-lengths 1·54 A., the photograph obtained with electrons, the energy of which corresponds to a wave-length of 0·06 A., and have a correspondingly greater resolving power, shows distinct rings, indicating the presence of tetragonal cristobalite crystallites constituting the vitreous silica.

By bombarding nickel with neutrons from a powerful radon-beryllium source, J. Rotblat has succeeded in producing radioactivity of two life periods, of twenty minutes and two hours respectively. He ascribes the longer-lived product to the formation of an unstable nickel isotope of mass 59 or 63, and the shorter radioactivity to radioactive cobalt of mass 60, formed from nickel-like atoms of the same mass. Mr. Rotblat has further obtained the radioactive cobalt of the same life-period by bombarding cobalt of mass 59 with neutrons.

Dr. V. V. Narlikar and K. V. Sastry direct attention to a new formula for a line-element, which may prove of great interest in the relativity theory of world-structure.

New measurements of the density of heavy water, by Dr. L. Tronstad, J. Nordhagen and J. Brun, give 1·10714 as the nearest approach to the correct value at 20°C. The authors suggest that the higher value obtained by Taylor and Selwood may be due to a higher proportion of heavy oxygen in the samples employed. The density of the purest light water (free from the heavier variety) was found to be 0·9999815.

Bacillus tumefaciens injected into the stems of tomato plants produces characteristic tumours of a given average size. László Havas, by injecting aqueous solutions of sex hormones, finds that the average size of the plant tumours above the site of the injection increased, while those below the site of injection decreased. Further work is necessary before it can be determined whether the direction of migration of the hormone is constant, and whether it varies with physiological and toxic doses.

Vitamin C, added to sterile plant cultures, leads to an increase of 35–75 per cent in the dry weight of the plants, according to experiments reported by Dr. Synnöve v. Hausen. This increase is due to ascorbic acid specifically, and not merely to the addition of an organic substance, since controls using glucose produced no such increase. The greatest differences were obtained during flowering.

Recent publications by Prof. H. Reed and Mlle. Frémont from the Citrus Experimental Station, University of California, confirm views expressed in NATURE by Dr. M. C. Rayner respecting the practical significance of the mycorrhizal habit in *Citrus* cultivation. The necessity for expert diagnosis in other crop plants showing similar root relationships is urged.

Research Items

Geological Age of the Markleeberg Palæolithic Industry

THE distinctive palæolithic industry found in the gravels of Markleeberg on the right bank of the Pleisse, approximately 8 km. south of Leipzig, of which examples were first collected in 1895, and of which accounts have appeared on numerous occasions since 1911, has given rise to much controversy owing to an apparent contradiction between its position in the geological time-scale and its relation to the culture sequence of the French archæological classification. On typological grounds, the industry is regarded as a Mousterian which retains certain primitive characters in its technique and shows Acheulean influences. In a discussion of the geological evidence of the age of the deposits in which the industry appears M. R. Grahmann points out (*L'Anthropologie*, **45**, 3–4) that difficulty arises, to a great extent, from the fact that the quaternary geology of the area is only very imperfectly known. Recent research has shown that there is evidence of three glaciations, corresponding to those of northern Germany, which may be termed Elster, Saale and Vistula. Applying this scheme to the Markleeberg deposits, the evidence is interpreted as indicating the moraine of the second glaciation, the Saale, as the source of the industry. Probabilities, however, point to the industry being older, while the diversity of facies it exhibits may well be due to the moraine having gathered up the debris of a number of sites of different ages. A suggested correlation of this scheme with that of the Alpine and north European glaciations equates the Markleeberg industry with the beginning of the Riss glaciation and makes it contemporary with the French Acheulean, thus indicating a difference in the course of development of stone age industries in central and eastern Europe and the west, while tending to support the view that the former were the earlier.

Agricultural Ceremonies in the Naga Hills

IN a communication dealing with the effect of ritual upon industries and arts in the Naga Hills, Mr. J. P. Mills (*Man*, **144**, September) describes the agricultural ceremonies observed by the Nagas during the year, which have not previously been recorded. The village is a closely knit community which acts together in seeking the favour of the spirits for the crops of all. The essential act of worship is a day of rest, on which no one is allowed to work in the fields. In all, there are about seventy *kennü* days in the year; but they are so arranged as not to interfere with agricultural operations. Thus in those months when the people are busily engaged in clearing the ground, sowing the millet or preparing for the growing of the important rice crop, few *kennü* days are observed, except here and there for rest from the work in hand. The close of a time for a particular operation, such as, for example, of the season of pot-making in January, is marked by a day of rest. Private ceremonies, from the nature of the case, do not show the same consideration for agricultural operations, and the observance of the days of abstention, such as are enjoined for sickness, a birth or death, make serious demands on time which may extend to as much as five days at a time. The agricultural year opens in January with three days of purification, after which the clearing of new *jhums* and the sowing of millet begins. In March, when it is time to think of the rice, four days between March 10 and 15 are days of *kennü* and feasting preparatory to beginning the main work of the year. At various dates in the following months there are *kennüs* to avert bad luck or damage from various causes, such as hail, grubs, ants, etc. Jungle clearing is accompanied by a great deal of feasting and jollification. *Kennüs* take place on September 10 and 11 for the solemn eating of the first fruits, and on November 24–December 5 the whole village gives itself up to the great feast which marks the end of the year's work.

Cobalt and 'Coast Disease' of Sheep in Australia

As is well known, minute amounts of certain elements, for example, copper, manganese, zinc, boron and others, are necessary for the normal nutrition of animals and plants, and evidence has been obtained that 'coast disease' of sheep in South Australia may be due to a deficiency of cobalt (Marston and Lines, *J. Council for Sci. and Indust. Res.*, Commonwealth of Australia, **8**, No. 2, pp. 111–117). In this disease, sheep fed on certain pastures become lethargic and anæmic, waste and ultimately die. The soil in the area is deficient in certain elements, notably phosphorus, but additions of iron, manganese, arsenic, copper and phosphates failed to cure or prevent the disease. Other elements were also eliminated, and as cobalt had been found experimentally to increase the number of blood-corpuscles, it was decided to test the effect of this element. Two sheep which were almost *in extremis* with coast disease were therefore given 1 mgm. a day of cobalt in the form of cobaltous nitrate. The effect was almost immediate; within three days the animals improved in health, appetite and body weight, and in the condition of the blood, and within ten weeks had become almost normal again.

Mollusca of Lake Geneva

AN interesting study of the ancient and modern molluscan fauna of Lake Geneva is made by M. Jules Favre ("Études sur la Partie Occidentale du Lac de Genève. 2. Histoire Malacologique du Lac de Genève". *Mem. Soc. Phys. et d'Hist. Nat. Genève*, **41**, Fasc. 3, 1935). Many species are discussed, but of special importance is the variability of *Valvata piscinalis*, which is very different at different depths. Two forms are found now living in the lake, the form *antiqua* having a thick and opaque shell, greyish yellow, pale, turriculated, with scarcely any umbilicus, which is distributed almost everywhere on the muddy bottom of the littoral and sub-littoral zone down to about 25 metres, then becoming scarce and disappearing at 40 metres, and the form *alpestris minor* having a whitish shell, diaphanous or almost hyaline with conspicuous transverse striations and large umbilicus, a much smaller form than *antiqua*. The form *alpestris minor* is now rare in the lake and localised in the vicinity of certain fields of Characeæ in the Bay of Belotte between 5·50 and 10 metres. It represents the primitive form occurring in the post-glacial sediment which has given rise to the common form *antiqua*, the latter being the best adapted to

littoral regions, thriving in the sub-littoral zone where it is not battered by the waves and tending in the littoral regions to be the typical form of *V. piscinalis*. The species established itself in the lake in Post-Glacial times very soon after the retreat of the glaciers, and was among the first of the molluscs to invade the sub-littoral region, rapidly undergoing important developments and varying greatly when large masses of Characeæ filled a certain part of the area, these algæ having a profound influence on the species. Then the original form varied in different ways according to its habitat, those on the muddy bottoms after much variation giving rise to the turreted *antiqua* with constricted umbilicus, now the commonest form to be found in the lake, those in the *Chara* beds being mainly planorbis-like flattened forms with large umbilicus. The form *alpestris minor* recalls the ancient population, and is only to be found in the fields of Characeæ.

Australian Cowries

COWRIE shells, popular with amateur collectors because of the beauty of their texture and patterns, have been well illustrated in colour in well-known monographs by the earlier workers. The difficulty of observing the living inhabitant, on account of the readiness with which it withdraws into its shell, has for the first time been overcome on a large scale by the Australian naturalist, Melbourne Ward. He has observed and made paintings of twenty species which he kept alive in his aquarium, and the paintings have served to differentiate species which on shell-characters alone seemed to be indistinguishable. Coloured figures of the living animals and their shells, with adequate descriptions, have been published in a complete list of Australian cowries (Cypræoidea) by Tom Iredale (*Australian Zoologist*, 8, 96; 1935); and the animals are even more beautifully coloured than their shells.

Development of May-Flies

IT has long been known that certain species of Ephemeroptera, or may-flies, pass through a very large number of nymphal instars. In this respect, they only find their parallel, in other insects, among the Plecoptera or stone-flies. An account of the post-embryonic development of several species of may-flies by Mr. F. P. Ide has recently appeared (*Canad. J. Res.*, 12, 433, April 1935). The life-histories of *Stenonema canadense* and of *Ephemera simulans* are described in detail, and those of nine other species less completely. In *S. canadense* the number of ecdyses was found to be between 40 and 45 and in *E. similans* about 30. At each moult there is some increase in size, but the significance of moulting seems to be primarily for the purpose of changing morphological structure. Every change in external structure, even to the addition of a single seta, can only be accomplished through ecdysis. The determination of the instars is stated to be possible owing to the fact that each moult results in a change in the number of segments in the caudal filaments. The author comments upon the fact that many other insects grow to a much greater size than may-flies and yet only pass through four or five moults. He concludes that it is unlikely that so many moults could be concerned primarily with increase in size and that the reason seems to be in the need for the nymph to be constantly changing its structure in order to adjust itself to environmental changes.

Intertidal Ecology

THE study of the habits and distribution of the animals and plants inhabiting the intertidal region of the shore is one of considerable difficulty on account of the complexity of the environmental factors involved. Where many factors such as wave-exposure, emersion and immersion, insolation, etc., are concerned, it is desirable to study localities with as simple conditions as possible. Kitching (*Trans. Roy. Soc. Edin.*, 58, Pt. 2, No. 15, 1935), in describing a number of places on the Argyll coasts, has related the size and abundance of some of the most important species of animals and algæ to wave-exposure, level and angle of slope of the rock. He also gives some data with regard to the hydrogen ion concentration, oxygen content and temperature in the various places. While some of the relationships are comparatively simple, such as the limiting wave-exposure which some algæ can stand without being detached, or the inability of barnacles to survive within the 'sweep' of the larger brown algæ, many of the relationships are very much less obvious, and collection of many more observations of this nature will be necessary for their elucidation.

A Rare Carnivorous Plant

DR. JOJI ASHIDA has given a very full account (*Mem. Coll. Sci., Kyoto Imp. Univ.*, B, 9, No. 3, Art. 5; 1934) of the opening and closing mechanism of the leaf blade of *Aldrovanda vesiculosa*, L., an animal-catching mechanism which has very seldom been studied, and never so thoroughly. Dr. Ashida was successful in growing this plant in culture throughout the year, the presence of dead leaves and stems of certain other aquatic plants proving to be the special requirement of this plant. The motile zone of the leaf blade lies at a distance of 0·15–0·25 mm. from the midrib and works apparently as the result of a loss of turgor of the inner epidermal cells on stimulation. The outer two layers, still turgid, then bend the two lobes so as to shut the leaf. After shutting, the surfaces are still compressed closer together, narrowing the cavity which encloses the animal victim. This is due to an increase of turgor and an active elongation of the outer epidermal cells; the water needed for the movement enters mainly through the outer surface. The subsequent expansion of the cavity within the closed leaf lamina and opening of the leaf is attributed to a transverse growth of the inner epidermis.

Distribution of Earthquakes in New Zealand

THE seismic record of New Zealand begins in 1848, and, from that time until the end of 1934, more than 6,000 earthquakes have been reported from various parts of the country. The distribution of these earthquakes, as regards both frequency and intensity, has recently been studied by Messrs. L. Bastings and R. C. Hayes (*Wellington Dom. Obs. Bull.*, No. 95; 1935). They divide the whole country into 19 areas roughly equal in size by lines of latitude and longitude. In the frequency map, the areas are shaded in tints depending on the percentage of the total number of New Zealand earthquakes felt within them. The highest percentage, 26·0, is reached in the district visited by the Murchison earthquake of 1929. A percentage only slightly less, 25·6, marks the western half of the central portion of the North Island, but this is due to the occurrence of more than a thousand

ocal shocks in and near Taupo in 1922. The district including Hawke's Bay has a percentage of only 9·0. The second map represents the maximum intensity of the earthquakes in the different areas, in six of which, at the north end of the South Island and the southern portion of the North Island, the tenth or highest degree of the Rossi-Forel scale was attained.

Theory of Elastic Solids in Practice

THE problems that arise when applying mathematical analysis to the stresses and strains in elastic solids only admit of exact solution in a few special cases. The demand for more accurate solutions has recently become urgent in the design of large electrical machines, as, owing to the improved methods of cooling now adopted, the permissible output has been greatly increased, and consequently the determination of the stresses and strains has become of primary importance. In the *Journal of the Institution of Electrical Engineers* of August, R. Poole discusses the various forces—magnetic, gravitational and mechanical—which act on the frames of large machines. It is pointed out that the effect of the magnetic pull on the frames is of great importance. He gives a method of analysis for calculating these effects which will be useful in practice, since it provides a means of showing the safe wear on the bearings of a machine and thus fixes the limits of mechanical design. As a check upon certain of the assumptions made in the mathematical treatment of the problem the author carried out photo-elastic tests upon model frames made of celluloid. The coloured photographs shown enable the distribution of the stresses and their approximate magnitudes to be seen at a glance. It is interesting to remember that these photo-elastic methods are based on the discovery made by Sir David Brewster that when a piece of glass is stressed and viewed in polarised light under certain conditions, brilliant colour effects are produced owing to the glass becoming double refracting. Prof. E. C. Coker has recently perfected an apparatus for this method of testing.

Stress and Elasticity

AMONG the papers issued by the Institution of Mechanical Engineers for written discussion (to reach the secretary before October 31) are three which are of general interest to physicists. In one of these, Dr. W. A. Scoble, the reporter, presents the fifth and final report of the Wire Ropes Research Committee, which, besides dealing with further series of tests made on ropes of different construction subjected to various degrees of loading, bending, lubrication, etc., contains an appendix reviewing the work of the Committee. This brief statement authoritatively corrects several misconceptions, particularly regarding the true factor of safety, and provides a guide as to the best conditions under which to employ wire ropes. In "Stress Waves in the Tyres of Locomotives", Prof. E. G. Coker and Dr. M. Salvadori exhibit and explain a photo-elastic investigation of the stress wave travelling in a locomotive tyre. The effects of the rail, the chairs, the spokes and the balance weight are shown in a series of diagrams. Dr. David Robertson presents a paper, "Hysteretic Influences on the Whirling of Rotors", in which are summarised the known facts concerning elastic hysteresis. It is shown that this can produce whirling when the shaft is running above its critical speed, and that the action of clamping fits, couplings and endwise friction may tend to produce similar effects. An approximate quantitative theory is evolved.

Steam Turbines

UNDER this title, the Association of Engineering and Shipbuilding Draughtsmen has issued a paper by C. S. Bradshaw (London: The Draughtsman Publishing Co., Ltd.). The series of printed pamphlets, to which it is the latest addition, consists of papers written by practical men for the use of others engaged on similar work, and the present issue is in full keeping with this tradition. The author is concerned at each stage of his examination of the subject with making typical calculations for the guidance of his reader. After treating in detail the several principles involved in the utilisation of steam in an engine of this kind, he proceeds with the preparation of the provisional design for a 3,000 k.w. impulse turbine to the extent of determining the steam consumption, efficiency and details of nozzles and blades. The author also explains the advantages of extraction turbines as developed to meet the case where, in addition to power, a supply of low-pressure steam is required for heating or industrial purposes, showing that in a particular case a saving of nearly 25 per cent in fuel may be effected. As to future design, his view is that a primary turbine will operate in the range from 3,000 to 600 pounds per square inch, the steam then passing to the main turbines, an arrangement which he considers would raise the overall station efficiency from the present figure of 26 per cent to one of 35 per cent.

Furfural Yield of Uronic Acids

THE separation of hemicelluloses from other plant constituents is a matter of some difficulty, and no satisfactory criteria of purity or homogeneity exist. Plant gums, which are also polyuronide in nature, have similarly been found to be complex mixtures without any sharply defined differences of properties. It has, however, been customary to determine the relative amounts of the major constituent groups in such preparations. By determining the evolution of carbon dioxide on distillation with 12 per cent hydrochloric acid an accurate figure for the uronic acid content is obtainable. Furfural determinations similarly give an estimate of the pentose content. Because it is known that uronic acids also yield some furfural under the conditions of that determination, a correction has been applied by many workers, based on an assumption that the yield of furfural from a uronic acid is $\frac{1}{6}$. Norris and Resch at Birmingham have critically examined this point (F. W. Norris and C. E. Resch, *Biochem. J.*, 29, No. 7, 1590; 1935) and find this assumption to be incorrect, the true value being considerably higher, and moreover influenced appreciably by the presence of other units such as hexoses. The significance of their observations will be realised when it is stated that the commonly accepted formula for pectin depends on a calculation employing the earlier erroneous factor. The conclusions of many other researches on the composition of hemicelluloses, mucilages and gums may have to be revised for the same reason. The effect of the use of the lower factor has been to cause the pentose content to be overestimated and the hexose content under-estimated. This is more serious in the case of pectin and certain gums of high uronic content than in the plant hemicelluloses, the uronic content of which is much lower.

Fire-walking

AT the suggestion of the secretary of the Institute of Physics, I attended the demonstrations of fire-walking by the Indian, Kuda Bux, on September 9 and 17. Notes on some physiological aspects of the second demonstration were published in NATURE of September 21, p. 468. One important detail should, however, be added, the time of contact of the performer's feet with the fire, which was certainly much less than five seconds.

Observations made at the first performance indicated that the feat was merely another form of the fireside experiment of picking up a hot cinder and returning it to the fire, when the fingers are not burnt, if the action is performed quickly. It, therefore, seemed probable that measurements of the rise in temperature caused by contacts of a cold substance with the fire, of similar duration to those of the walker's feet, would test the correctness of this view, and preparations were made to do this at the second trial on September 17. On this occasion, Dr. T. E. Banks, of the Physics Department, St. Bartholomew's Hospital, and Mr. G. Smith, of the London School of Hygiene and Tropical Medicine, collaborated with me in making the observations.

These comprised the measurement of the total time of contact of each foot with the hot surface; counting the number of steps; and then pressing a thermal junction on to the fire intermittently so as to imitate the period of contact of each foot and the interval between each step, the rise in temperature then being noted on the indicator. The junction consisted of a thin disc of copper, to which wires of copper and eureka were fastened. The wires were passed through holes in a piece of uralite and pulled, so as to bring the disc into contact with the uralite, so that when the disc was pressed on the fire the conditions were favourable for the absorption of heat and its retention when the junction was raised for another impact.

The arrangement was equivalent to a sensitive walking thermometer, and would certainly show a greater rise in temperature under the same conditions than the human skin, which is protected by the moisture it exudes.

Careful observation with a stop-watch having shown that the average time of contact of the walker's foot was half a second at each step, and it being noted that each foot rested twice on the surface during the passage, the junction was struck on to the surface twice in succession, a period of contact of half a second per impact being attempted. Actually, owing to the difficulty of working near the fire, this period was always exceeded, but a number of separate trials showed a rise of 15°–20° C. in the junction. This was conclusive evidence that the feet of the performer would not become hot enough for blistering to occur.

Fire-walking is really a gymnastic feat, and the agile way in which Kuda Bux walked across the fire compelled admiration, and would be difficult to imitate without much training. It would not be easy for a beginner to walk bare-footed over cold charcoal so as not to exceed the time of contact necessary for successful fire-walking. It was lack of training in this particular which prevented Mr. Moynagh and Mr. Sheepen from succeeding; but it was noticeable that even in their cases large portions of the feet were uninjured. Both were much heavier men than Kuda Bux, and this caused them to sink more deeply into the fire, and increased the time of contact. A temperature-measuring device conforming more nearly to the conditions of the skin could be made and tested on a fire, but the explanation of fire-walking is so obvious that this would be superfluous.

CHAS. R. DARLING.

Work of the Rothamsted Experimental Station

AN event of great importance in the history of the Rothamsted Experimental Station occurred in 1934, namely, the purchase of the farm and adjoining lands by the Rothamsted Trustees. Few people perhaps realise that hitherto this experimental centre, with its long-term trials known the world over, was held only on a lease, and that it was threatened by the encroachment of the builder. The sum necessary for purchase was speedily raised by public subscription. A glance at the subscription list gives ample testimony, if such were needed, of the high esteem in which the Station is held by farming organisations and business men. It is not out of place perhaps to mention here that unique organisation—the Society for Extending the Rothamsted Experiments—which was founded in 1904. This Society has not only helped financially, but, by looking ahead, has also enabled important work to be initiated without the delays that usually occur if the money question is left until it is time to start work. Among the many old and modern documents in the Station library, the minutes of this Society will be among the most interesting in years to come.

The report for 1934* opens with an account of the continuation of the experiments on yield and quality in sugar-beet, potatoes, wheat and barley. In the sugar-beet work it is pointed out that most of the information available on this crop applies to Continental conditions, and that it by no means follows that recommendations suitable abroad are applicable in Great Britain. Thus, in these trials, potash and phosphate appear to have but little effect, a result that would scarcely be expected from the data that are available on this crop.

The work on organic manures continues, and shows

* Rothamsted Experimental Station: Lawes Agricultural Trust. Report for 1934. Pp. 259. (Harpenden: Rothamsted Experimental Station, 1935.) 2*s.* 6*d.*

that there is a considerable amount to be learnt about green manuring; the investigators, however, appear to be nearer to explaining the negative results, noted in the 1933 report, obtained by the use of green manures on the light soils of Woburn. The trials with poultry manure, commenced in 1933, have been continued with market garden crops, the manure having been compared with equivalent mixtures of sulphate of ammonia and superphosphate; the nitrogen in the dried poultry manure did not prove so valuable as the nitrogen of sulphate of ammonia.

A valuable feature of the report is provided by articles on the contribution of the various departments to the study of soils and crops. Thus, work on soil physics is reported on by Dr. B. A. Keen, and that on the chemistry of soils and fertilisers by Dr. E. M. Crowther; the contribution to soil bacteriology is discussed by Dr. H. G. Thornton, and that on general microbiology by Mr. D. W. Cutler. In the Soil Physics Department, much attention has been given to the study of the plastic behaviour of soil and clay, work which is of interest to the ceramic industry as well as to the cultivator of the soil. Among the results of theoretical interest may be mentioned the grave doubts thrown on the reality of 'structure turbulence' and 'structure viscosity' in soil and clay pastes—subjects that have been extensively studied by other workers. In practical soil cultivation, the work touches aspects such as ploughing speed, and tilth. In the section dealing with soil cultivation, great importance must be attached to the studies on the effects of rotary cultivation. This method of tilth production is entirely new, and of great promise; the work at Rothamsted will give advisers and investigators definite information upon which to work. In Dr. Crowther's contribution, special interest is attached to the hypothesis which is put forward that, in a heavy soil, nitrate washed out of the surface may be stored in the structural units of the subsoil. To quote this report, "it seems possible that this hypothesis may serve to bridge the gulf between the pedologist's concern with the deeper horizons and the analyst's use of surface samples".

The Manager's report on the Rothamsted and Woburn farms, together with the notes on the weather, and on the insect and fungoid pests could not fail to interest any farmer. Indeed, the Rothamsted annual reports, in addition to their value to the agricultural scientific worker, can be recommended as deserving a place on the bookshelf of all intelligent farmers.

American Universities and Game-Rearing

THE American universities have been conspicuous in their pioneer additions of practical subjects to the university curriculum, and it is particularly interesting, therefore, that, as J. N. Darling, Chief of the Bureau of Biological Survey, U.S. Department of Agriculture, describes in a paper in the September issue of *Scientific American*, 30,000 dollars for an endowment fund for five years has been offered by an anonymous U.S. arms' manufacturer to the Biological Survey for wild-life restoration and administration training at several of the State universities. It has been announced that several State universities are to set up courses in game management with the active support of the Bureau of Biological Survey, which will supply instructors and contribute 42,000 dollars; State and game conservation organisations will also combine in the scheme, and original research in wild-life subjects will be incorporated in the training course, as is done with the forestry training.

"The reservation of enough grazing lands to maintain a reasonable supply of our big game animals can be accomplished without infringing upon the reasonable requirements of the stock growers", Mr. Darling states. "The same is true of small game species. A few large reservations of the hereditary ranges, supplemented by development for wild-life purposes of waste lands, of odds and ends such as ravines, sloughs, roadside strips, fence rows and sub-marginal tracts will be sufficient to bring back wild creatures even in our intensively cultivated areas in more abundance than has been observed for two generations. . . . On most land midway between fertility and barrenness, fish, game and furbearers can exist with far better profit to humanity than when given over to a desperate sort of agriculture. Throughout the U.S. the total drained areas equal 110,000,000 acres."

Wild-life and game animals, and especially non-migratory birds, have decreased markedly in the United States during this century, owing to extensive shooting with little organised game protection or conservation. Ten years ago, Maine alone produced more mink pelts than are now annually produced in all the United States. The trumpeter swan is confined to a few haunts, of which Yellowstone National Park is one. With State and Federal aid, a herd of 20,000 elk still exists in the Jackson Hole region of Wyoming. Within recent years the "More Game Birds in America" Foundation was formed and incorporated in New York to increase American game by the control of their natural enemies and the following of intensive game-rearing on lines similar to those adopted in Europe, particularly Great Britain, where since the passing of the Game Act of 1831, partridge have increased more than 200 per cent and pheasants more than 1,000 per cent, and in the six years 1919–25, after War-time diminution, British gamekeepers increased the nation's stock of game-birds by 900 per cent.

In 1934, Prof. A. A. Allen, of the chair of ornithology at Cornell University, succeeded in rearing ptarmigan in captivity for the first time, hatching eggs obtained in the Hudson Bay region, under bantams. The Bureau of Biological Survey already possesses divisions studying water-fowl numbers, game conservation, predatory animal and rodent control, fur resources, with considerable numbers of reserves and stations, and there is an Alaska Game Commission. Bag limits are made to protect wild geese and other birds in many States, and methods of hunting and shooting are under legal control in many States.

Royal Photographic Society

ANNUAL EXHIBITION

TO the man in the street the results of photography are 'pictures' of one sort or another, but mainly intended to be artistic. The eightieth Annual International Exhibition of the Royal Photographic Society usually emphasises in the mind of the visitor this artistic aspect of photography; in the principal gallery, for example, are one hundred and seventy large prints, all of pictorial character, whilst in another room are more than two hundred pictorial lantern slides. Photography is, however, both a science in itself and a good servant to most other sciences. This exhibition gives a suggestion of its varied problems and applications.

This year the Eastman Pola light filters seem to be the outstanding example in the exhibition of a photographic problem solved. These filters incorporate a plane polarising material and can be manufactured in sizes large enough to cover camera lenses, and even light sources. They can be used to eliminate the glare, due to surface reflection, from all sorts of objects. Some excellent examples of this are shown, notably some photographs of polished carving and of an oil painting. In the latter, reflections from the brush-marked surface are completely eliminated. Interesting effects are also shown to be produced when one filter is placed over the light source and another, crossed with relation to the first, over the camera. For this exhibit, the Hood Medal has been awarded to Edwin A. Land.

Of educational exhibits is one by P. C. Smethurst illustrating the growth of convection currents from an electric heater immersed in a tank of water. Prints of individual states are shown and a 16 mm. motion film has been made. In another educational film, L. A. Jones shows, by the new Kodachrome colour process, growing crystals photographed through a polarising microscope. A medal has been awarded for this film.

Nor do the technical exhibits of some photographic manufacturers lag behind in explanatory value. The enormous exposure range of modern photographic materials used for ordinary photography is well illustrated by Ilford, Ltd. The same theme is taken by the Eastman Kodak Co. in relation to their automatically controlled reversal process for sub-standard cinematography. Another exhibit by Ilford, Ltd., illustrates the use of special materials for recording atomic disintegration and for mass spectrography.

In colour photography several processes are represented. Agfa Colour, Finlay, Dufay Colour and Kodachrome, of the colour transparency processes, are all represented, whilst for colour prints on paper examples of Tricolour Carbro, Vivex, Raydex and Duxochrome may be seen.

High-speed photography is this year well represented by studies of a football as it is kicked, and a tennis ball at the impact of the racquet—the ball is almost hemispherical. Exposures of 1/100,000 sec. were used for these (K. J. Germeshausen, H. E. Edgerton and H. E. Grier). Another excellent series by A. M. Rothrock and E. C. Buckley records for the first time the injection and combustion of the fuel in a high-speed Diesel engine; for this a special motion picture camera is used in which the time interval between frames is 1/2,500 sec.

Swelling of Colloids

IN the August number of the *Berichte der chemischen Gesellschaft*, Prof. H. Staudinger and Herr E. Husemann describe interesting experiments on the behaviour of certain polymerised olefines towards solvents.

It is a remarkable fact that among colloids of high molecular complexity one may find substances apparently identical in composition but possessing very different properties. In a previous paper (1934) it was shown that styrene yields two dissimilar polymers, one of which swells continuously in a given solvent until it dissolves completely, whereas the swelling power of the other is strictly limited. In the latter case, the original form of the polymer is retained after swelling, although the volume may be increased fifty- or hundred-fold, but it remains undissolved. It was found that this insoluble variety with limited swelling power is only produced when small amounts of divinylbenzene are present in the styrene, and the theory was advanced that the soluble form consists of long thread-molecules, whereas in the other case more complex 3-dimensional structures are formed.

Further study has shown that the thread-molecules are long, rigid, elastic structures, not easily deformed but soluble forming viscous solutions. When these threads are linked together by divinylbenzene bridges they may form insoluble 3-dimensional molecules unless the amount of bridging is very minute, when the effect is to produce still longer soluble threads. The products with limited swelling-power are now regarded as tangled, felted mixtures of insoluble bridged products with soluble threads. Complete extraction of the threads by the solvent is prevented by the felting. The investigation of these complex polymers has necessitated the development of a special technique, for which we are mainly indebted to Prof. Staudinger. Methods have already been worked out for the synthesis of a kind of homologous series of colloidal polymers, which are classified according to their molecular dimensions as (1) hemicolloidal, (2) mesocolloidal and (3) eucolloidal polystyrenes with molecular lengths of 20–250, 250–2500 and 2500–10,000 A. respectively. The authors have made an elaborate study of the polymerisation under varied conditions of pure styrene and divinylbenzene and of mixtures of these.

In every case the degree of polymerisation was determined by viscosity measurements, and it has been found possible to determine the minimum amount of divinylbenzene required to produce a polymer with limited swelling-power.

Educational Topics and Events

BIRMINGHAM.—Colonel H. F. Humphreys has been appointed to the recently created chair of dental surgery. He was formerly lecturer in dental anatomy and curator of the Odontological Museum in the University.

CAMBRIDGE.—The following committee has been appointed to advise the Council of the Senate in their choice of a Jacksonian professor of natural philosophy :—the Vice-Chancellor, W. Spens, Prof. Lennard-Jones, H. Thirkill, Prof. G. I. Taylor, Sir Frank Smith, Lord Rutherford, Sir William Pope and Lord Rayleigh.

The following resignations or retirements are announced :—J. T. Saunders, lecturer in zoology ; A. A. Miles, demonstrator in pathology ; Dr. A. E. Barclay, lecturer in medical radiology and electrology ; T. G. Room, lecturer in mathematics ; Dr. J. Chadwick, lecturer in physics ; Dr. N. Feather, demonstrator in physics; H. N. Green, demonstrator in pathology; R. H. D. Mayall, lecturer in mathematics ; Dr. G. F. C. Searle, lecturer and demonstrator in physics ; Dr. S. M. Manton, demonstrator in comparative anatomy ; E. H. B. Boulton, lecturer in forestry.

R. Passmore has been elected Gwynaeth Pretty student, and Dr. M. E. Adair, of Girton College, John Lucas Walker student.

The John Wimbolt Prize has been awarded to E. D. Ward, of Gonville and Caius College, for a dissertation on "The Thermal Properties of Metals and their Engineering Significance".

At St. John's College, J. S. Marshall, Queen's University, Ontario, has been elected to an exhibition for physics, and G. H. Twigg, University of St. Andrews, to one for chemistry.

At Emmanuel College, the external studentship has been awarded to J. C. Bower (University of Melbourne), for physics.

AN account of the development of the Department of Industrial Administration in the College of Technology, Manchester, by Dr. K. G. Fenelon, has been reprinted from the "Year Book" of the Manchester College of Technology Old Students Association. The Department was founded in 1918 through the co-operation with the governing body of the College of eleven firms each of whom contributed an annual sum of £100, and was developed with the special object of providing facilities for training in the broad underlying principles of management and administration. For the first few years, the Department's activities under the direction of Dr. Stanley Kent were largely devoted to research, but Mr. Dempster Smith who succeeded him as director in 1921 proceeded to develop the teaching side. Evening courses were then established, including those on administration for engineers and administration for chemists, and a full-time two-year day course in industrial administration was introduced, which in 1926 was recognised for the associateship of the College. In 1926 a University post-graduate course in industrial administration was commenced, the first course of its type to be provided in Great Britain, and in the same year the Department was taken over entirely by the College, the original guarantors, with certain changes, continuing to act as an Advisory Committee. Dr. James A. Bowie succeeded Mr. Dempster Smith as director in 1926 and was followed in turn by Dr. K. G. Fenelon in 1931. Research at present in progress includes scientific management in textile mills, budgetary control, works organisation with special reference to engineering industries and administration and organisation of transport enterprises. Experiments have been made with the 'case method' of instruction, and the full-time courses include weekly study visits to factories, offices and business enterprises.

SCHOOLS of the largest size are to be found, as is well known, in American cities. A recent monograph on the elimination of very small schools (Bull. No. 3, 1934, of the Office of Education) reveals the surprising facts that in the United States more than 7,000 State schools have not more than five pupils each and 1,000 have only one or two. Moreover, in some States the number of such very small schools tends to increase with the substitution of larger farms for smaller and rural depopulation. At a time when school costs are bearing heavily on reduced revenues, the expensiveness of maintaining these diminutive units is directing attention to various schemes for eliminating them. Consolidation into larger units of the ordinary type is among many communities impracticable because transportation facilities cannot be provided. Considerable interest has in recent years been aroused by the use of postal tuition for secondary education, and the question has now been raised whether such correspondence lessons might not with advantage replace many of the excessively small and costly rural schools. Australian and Canadian public school administrators are well satisfied with the results of primary education by correspondence under schemes which have been in operation for some fifteen years in Australia and British Columbia and seven years in Alberta, Saskatchewan and Manitoba. A comprehensive account of the Australian schemes was published in 1931 by Melbourne University Press in association with Messrs. Macmillan and Co., Ltd. The author, Dr. K. S. Cunningham, while admitting that children so taught miss some valuable social experiences, was impressed by the compensating advantages accruing from the intellectual independence fostered in them through having to tackle their work without the present aid of a teacher.

Science News a Century Ago

The Association of German Naturalists

WRITING from Bonn on September 28, 1835, to the *Athenæum* about the German Society "Der Naturforscher und Aerzte" which had just finished its meeting, a correspondent said : "The proceedings of this body must necessarily excite an increasing interest, when its offspring, the British Association, has been growing to its present colossal dimensions, although the subjects and discussions at these Meetings are less comprehensive than at the Association, being confined to Natural History in its widest extent, Anatomy and Chemistry. The results of both have been crowned with a success little expected by those who projected them". Among the most distinguished men of science at Bonn were Von Buch, Elie de Beaumont, Constant Prevost, Alexandre and Adolphe Brongniart, Littrow, Audouin, Ritter, Jussieu, Ampère and Weber, the British men of science including Buckland, Lyell, Horner, Greenough, Gregory and Turner. The first

general meeting was held on September 18; the sectional meetings began on September 19. There were various expeditions, and during the last of these on September 26 Buckland and Von Buch were hurt in a carriage accident.

Writing of the papers in the Sections, the correspondent of the *Athenaeum* said: "The Geological was, as usual, the most popular. The question of elevated craters relating to the much-disputed theory of Von Buch, was discussed at length, and somewhat hotly, the leading speakers being Elie de Beaumont, Lyell, Prevost and Von Buch himself." Very beautiful drawings of Etna and Vesuvius were exhibited and described by Dr. Abich, of Brunswick, while among other topics discussed were Schmerling's discoveries in the bone caverns of Liége, Van Hoff's remarks on the footmarks in sandstones at Hildberghausen, and Buckland's views on the Dinotherium and on the identification of certain beds south of Liége with the Silurian system of Murchison.

"The disposition to conviviality which you noticed in the account of the Dublin Congress was not wanting in Bonn; in this respect the family likeness is most striking: eating and drinking, and giving of toasts, were by no means the least important occupations of the day. . . . The last toast which was given at Bonn, was by Dr. Froriess, of Weimar, 'The British Association and its former president, Dr. Buckland', which was drunk with enthusiasm".

Littrow Observes Halley's Comet

ON October 17, 1835, *The Times* published the following note: "Vienna, Oct. 3. This morning Halley's Comet was perfectly visible to the naked eye as a star of the third magnitude, with scarcely any nebula about it. But seen through the telescope, it looked like an extensive nebula, the largest diameter of which was about 15 minutes, or half the diameter of the sun, with a very bright pretty scintillating nucleus, but still without any considerable tail. . . . As the light of the comet has so much increased within a few days, we may expect that it will be a very fine object in the second half of October. C. L. Littrow."

Baily's "Account of Flamsteed"

IN astronomical circles in 1835, the publication of Baily's "Account of Flamsteed" was regarded with an interest secondary only to that shown in Halley's comet. Admiral W. H. Smyth (1788–1865) was among the early readers of the book, and on October 3, 1835, he wrote from Bedford to Mrs. Somerville: "How remarkable that the month of August this year should rattle Halley's name throughout the globe, in identity with an astonishing scientific triumph, and that in the self-same month the letters of Flamsteed should have appeared! How I wish someone would give us a life of Newton, with all the interesting documents that exist of his labours! Till such appears, Flamsteed's statements, though bearing strong internal evidence of truth, are *ex-parte*, and it is evident his anxiety made him prone to impute motives which he could not prove. The book is painfully interesting, but except in all that relates to the personal character of Flamsteed, I could almost have wished the documents had been destroyed. People of judgment well know that men without faults are monsters, but vulgar minds delight in seeing the standard of human excellence lowered".

Societies and Academies

PARIS

Academy of Sciences, August 5 (*C.R.*, 201, 369–412). LOUIS DE BROGLIE and JEAN LOUIS DESTOUCHES: The theorem of Kœnig in wave mechanics. CHARLES NICOLLE and J. LAIGRET: Vaccination against exanthematic typhus by the living typhus bacillus, dried and coated. HENRI LAGATU and LOUIS MAUME: Variations of the physiological ratios in correlation with the disease of 'wild fire' in the tobacco leaf. Chemical differences are disclosed by the analysis of the healthy and diseased leaves, the alteration in the potash to nitrogen ratio being particularly marked. It is not yet clear whether the changes in the ratios are a cause, or a symptom, of the disease. SVEN GULDBERG: The formulæ of recurrence of the semi-invariants of Bernoulli's law and of Pascal's law with n variables. CONSTANTIN POPOVICI: The periodic solutions of S. Chapman's equation. G. BOURION: The ultra-convergence of integral series. RENÉ RETEL: Remarks on detonation in Diesel motors. The phenomenon has been studied using the Serruys optical manograph with small inertia, and, from the results, suggestions for avoiding detonation are deduced. It would appear that the presence of light products arising from cracking the fuel is the cause of detonation. MIROSLAV NÉNADOVITCH: The characteristics of certain rigid biplane cells of infinite spread. BENJAMIN GUREWITCH: A method for the study of magneto-strictive vibrations. PIERRE MESNAGE: The molecular emission spectra of some metallic salts. The spectra of the chlorides of iron, chromium and cobalt. ANTONIN ANDANT, PIERRE LAMBERT and JEAN LECOMTE: The diffusion spectra (Raman effect) and infra-red absorption spectra of saturated fatty alcohols and ethylene hydrocarbons. The Raman spectrum gives a characteristic line with the double bond: the infra-red spectrum gives two lines characterising the tertiary alcohol function. The two methods together distinguish between successive homologues and isomers. MAURICE BONZEL: The deformations accompanying the thermal treatments of cold-hardened metals. GEORGES ARDITTI: The autoxidation of normal hexadecane. Study of the oxidation of the liquid hydrocarbon at varying temperatures. For all the temperatures studied, the commencement of oxidation is accompanied by production of carbon monoxide in predominating amounts. More oxygen is used than can be accounted for in the gases produced. HENRI LONGCHAMBON: The structure of the Cevennes in the region defined by the Largentière sheet on the scale of 1/80,000. B. CHOUBERT: The Cretaceous formations of the coastal zone of Gabon. JACQUES FLANDRIN: Some features of the middle Eocene Algerian palæogeography. A. CHARLES HOLLANDE: The structure of the nucleus and its constituents: their homologation with the nucleosomes of the Schizophytes (Bacteriaceæ and Cyanophyceæ). HENRI COLIN and MLLE. ANDRÉE CHAUDIN: The diastatic hydrolysis, *in situ*, of the intercellular cement. EMILE MIÈGE: The constitution and descent of the polycarpic strains of *Triticum vulgare*. NICOLAS METALNIKOFF: The bactericidal power of water submitted to the combined action of metallic silver and a continuous electric current. The passage of a continuous electric current, 0·3–4 milliamperes under 1·5–4·5 volts, with a metallic silver anode, confers strong bactericidal

properties on water in a few minutes. Such treated water, after one to three hours contact, kills bacilli of coli, cholera, paratyphoid, typhoid and staphylococcus. The bactericidal property remains after boiling. No taste is imparted to the water, and from experiments on mice it would appear that it has no injurious effects on the organism.

Cracow

Polish Academy of Science and Letters, July 1. W. M. Jezewski, M. Wierzbicki and J. Kamecki: The dielectric constants of strong electrolytes of low concentrations at varying temperatures. The experimental results obtained with solutions of sodium chloride, potassium chloride, magnesium sulphate and barium ferrocyanide are in good agreement with the theory of Debye and Falkenhagen, if the orientation of the dipoles by the intense field of the ions is taken into account. T. Piech: The dielectric polarisation of some alums. B. Milianczuk: The radiation of a magnetic dipole. B. Milianczuk: The diffraction of light in the neighbourhood of the lines of the magnetic dipoles. Mme. W. Czapska-Narkiewicz: The absorption spectra and fluorescence of some coumarin derivatives. B. Kamienski and W. Goslawski: The influence of hydrogen ions on the dielectric potential and surface tension of solutions of some organic substances. L. Marchlewski and B. Skarzynski: Absorption of ultra-violet rays by certain organic substances (40). L. Marchlewski and B. Dabrowski: The determination of very small quantities of zinc by the spectrographic method. St. Kreutz: Calcites and other minerals characterised by their luminescence. K. Dziewonski, L. Gizler and J. Moszew: The reactions of some mixed aromatic ketones with bisubstituted thiourea derivatives containing different aromatic radicals. T. Domanski and J. Suszko (1): Some transformations of the isoquinidines. (2) Niquidine. H. Telezynski: Cytological studies on an unstable strain of *Petunia violacea*. St. Markowski: The parasite worms of *Gobius minutus* of the Polish Baltic. Mme. Irène Latinik-Vetulani: Experimental researches on anoxybiosis in the different stages of development of *Rana fusca*.

Rome

Royal National Academy of the Lincei, April 7. Margherita Piazzolla-Beloch: The asymptotes of a plane algebraic curve in relation to the theory of diameters. B. Colombo: An equation with partial derivatives of the fourth order. J. Rey Pastor: The quasi-continuous convergence of successions of functions. G. Marletta: Reflections on differential projective geometry. C. Tolotti: Einstein's gravitational equations for dynamic universes endowed with complete symmetry about a centre. A. Fenici: Centres of gravitation and centrobaric bodies. R. L. Gomes: A property of de Broglie's operator, H. O. Zanaboni: Determination of critical loads by means of the principle of virtual work. F. Zagar: The orbit of a third invisible body in a binary system. The utilisation of measurements of radial velocities to deduce the existence and the orbit of an invisible body revolving round one of the two components of a binary system is considered. Under definite conditions, it is possible to derive, not only the orbital plane of the invisible body, but also all the other elements except the major semi-axis. F. Odone: Thermodynamic foundations of the theory of electrical equilibrium and of the permaner currents in metallic conductors. F. Pierrone: Al cyclic compounds (1). Synthesis of β-ketoamines The products obtained by the interaction of benzal dehyde, ammonia and cyclohexanone indicate that in this reaction, the equilibrium between the enolic and ketonic forms of cyclohexanone is displaced towards the ketonic form. F. Dulzetto: New observations on the life and relation between the sexes in the young of *Gambusia holbrookii*, Grad. I. Delpino: Notes on the diffusion of *Trutta genivittata*.

Sydney

Royal Society of New South Wales, August 7. G. O. K. Sainsbury: Vegetative reproduction in New Zealand mosses. Twenty species are recorded as having peculiar brood-bodies or gemmæ on the leaves. These organisms become detached, and develop into a thread-like growth, and are eventually formed into lateral or terminal growths similar to what are known as bulbils. These structures are capable of developing into separate plants, and thus form populations by this means instead of the usual spore germination methods of reproduction.

Forthcoming Events

Monday, September 30

Royal Society of Medicine, at 5.—W. Trotter: "General Ideas in Medicine" (Lloyd Roberts Lecture).

Organisation of Agricultural Research

STATE assistance to agricultural research in Great Britain began with the Development Act of 1909, and in accordance with the principle of that Act, the finance of the schemes then initiated remained with the Development Commission, while the administration rested with the departments of agriculture, until in 1930 the Agricultural Research Council was set up. This council, though equally under the Privy Council, has not quite the same status as its parallel bodies, the Department of Scientific and Industrial Research and the Medical Research Council, both of which administer directly the whole of the funds available from the Treasury for research in their subjects. It would be difficult to explain to a foreigner the curious machinery which now prevails for the purpose of making grants, involving as it does the Research Council, the Development Commission, the two departments of agriculture in England and Scotland, and finally the Treasury.

A recent article in *Planning* is very insistent on simplification, on the ground that all these separate strands of red tape not only result in delay in the consideration of applications for grants, but also are obstacles to the proper planning of agricultural research. Of course, no one would devise such an organisation *de novo*; it grew by stages, its excuse is the dread all Governments have of legislation, its justification is the necessity of maintaining continuous touch between the research workers and the agricultural departments, the administration of which should be guided by the conclusions reached by research. It may be doubted whether delays are greater than in any other dealings with a Government department. Speed of action is the attribute only of an autocracy, and of an autocracy on a small enough scale to allow of immediate access to the autocrat.

As to planning, it was for that purpose the Research Council was set up; it surveys the whole field, it reviews the work of each Institute, and though that Institute may be financed by the Development Commission and administered by the Ministry of Agriculture, it would scarcely be able to ignore the recommendations or criticism of the Council. As the writer in *Planning* admits, the cumbrous organisation is being made to work, and so it will remain until there comes along some Government willing to spare some of its precious 'time' in order to secure order and logic in its machinery of administration.

The article also discusses the failure to obtain any substantial addition to the funds for research from the farming community, but that is inevitable because of the way the industry is split up into small units of production. The Marketing Boards do possess powers of making a levy on their very considerable turnover that would raise ample funds for research, without imposing any perceptible burden upon the individual, but the awkward administrative question of reconciling the responsibility of the Council for the direction of research with the power of the purse possessed by the Marketing Boards is still unsettled.

The most weighty criticism of the *Planning* article is directed against the indifferent scale of salaries prevailing in the research institutes, which it is alleged are failing to attract men of initiative and high mental capacity. But as the head of one of our universities has pointed out, only a small fraction of the men who graduate each year are really of the first grade, a fraction well below the demand that is made upon the universities by the various services, business and professions. When, however, all allowance is made for this and for the fact that research

offers a sheltered career with an attraction of its own, irrespective of income, there is undoubtedly much dissatisfaction among the agricultural research workers, a small body not more than five hundred in all, a large proportion of whom are not established. There is need for an unbiased review of the situation, and this is presumably within the reference of the Research Council. Agricultural research workers do need favourable terms, for they have few outlets for escape into well-paid business. It is precisely this alternative which renders recruiting for research in veterinary medicine so difficult in the veterinary profession; the great increase in administrative appointments of recent years has offered to any graduate of quality prospects much superior to those the research institutes can offer.

We doubt if the suggestion that the Research Council itself ought to appoint super-directors of its own for each group of subjects is helpful. The man in charge of a research station, the man who is immersed in the subject, may be guided and may benefit from the critical examination of his work by men of quality in the cognate pure sciences, but he cannot be made to work to order or forgo his responsibility. If one believes in research, one must trust the research worker's personality. The practical outcome of such a plan would be to withdraw the few outstanding men of originality from the active prosecution of research into administration.

The real function of the Research Council is not to control research nor to manage the research workers; it is to survey the field as a whole and to think out priorities, and to bring an enlightened judgment to bear upon the many proposals put before the Council. It has to decide whether the possibilities offered by the project are of the order of probabilities, and how far the pursuit of pure knowledge has an economic justification. Sometimes it will see a neglected opportunity, sometimes it must override a director in the interests of a more comprehensive organisation, sometimes it must advise a director that an investigation is becoming a routine, a blind alley. But ultimately it has to recognise that research is the product of the imagination and insight of individuals; its highest wisdom is to back the right horse.

Finally, the writer in *Planning* directs attention to the weakness of the organisation for getting the results of research passed over to the farmer and translated into action. It is a question which troubles the agricultural administration in every country, and particularly obsesses the public men concerned with agriculture. The inherent difficulty lies in the fact that agricultural production is split up among a number of relatively weak units, limited by lack of capital and personality. In agriculture there are no great corporations the resources of which enable them to take a long view about the adoption of a new process. The educational service which is in direct contact with farmers is outside the purview of the Research Council, and is doing excellent work. But the industry will have to become organised before it can reap the full harvest of research; as the Marketing Boards gain experience, they will be able to press upon the producers, their members, the improved methods that are the outcome of investigation and knowledge.

Study of Crystal Structure

A Study of Crystal Structure and its Applications

By Prof. Wheeler P. Davey. (International Series in Physics.) Pp. xi+695. (New York and London: McGraw-Hill Book Co., Inc., 1934.) 45*s*. net.

AFTER a rather quiescent period, the study of crystals sprang into great activity as soon as it was discovered that crystalline materials could be used as three dimensional gratings for radiation of the wave-lengths of X-rays. The earlier work of crystallographers on the theory of space groups was presented in forms more useful for the new developments by Wyckhoff and by Astbury and Yardley. The Laue and Bragg methods, and the powder photographic method, were employed in the analysis of the internal structures of the simpler substances, and the subject advanced at a rapid rate.

As the substances examined increased in complexity, more data had to be obtained to permit of the deduction of their structures. Rotation and oscillation photographic methods were developed, special types of camera designed and much ingenuity displayed in devising reasonably quick graphical methods of interpreting the photographs; as

examples, may be quoted, on the practical side, the Weissenberg camera, and, on the theoretical side, the conception of the reciprocal lattice.

The extension of our knowledge of atomic structure factors enabled considerations of the intensities of the reflected beams to add their full quota towards structure determination. The Fourier analysis method, first suggested by W. H. Bragg, was developed by many investigators and, in the hands of W. L. Bragg and his school, formed the basis of the determination of the structures of the complex silicate groups. All these problems are dealt with by W. P. Davey in the first half of this book. In view of the increasing importance of intensity measurement, however, it would have been appropriate, perhaps, to find room for some reference to improvements in intensity determinations of photographically recorded reflections.

If enough were known concerning the fundamental properties of matter, it ought to be possible to calculate the physical and chemical properties of crystalline materials, and in illustration the author considers the refraction of light by crystals, and more particularly W. L. Bragg's calculation of the optical constants of calcite and aragonite.

Atomic sizes, lattice energies, diffraction by amorphous materials, polycrystalline texture and solid solutions, all find their places in the text, but liquid crystals and fibre structures might have received more detailed consideration.

Of particular interest at the moment is the study of the imperfections of real crystals, that is, their deviations from ideal lattices. This involves much more than X-ray observations alone and, quite justifiably, a whole chapter has been devoted to this subject. It is unfortunate, however, that the chapter deals so fully with Zwicky's secondary lattices, a conception which is now generally considered to be built upon a rather unsafe foundation, while other hypotheses receive scant mention.

The volume concludes with four appendixes, of which the first gives a limited account of apparatus for the production of X-rays, the second deals with charts for use in the interpretation of powder photographs and the third records space group tables. The author disclaims any use for the Hermann Mauguin symbols, but, after devoting three pages to their reproduction, it seems a pity that he does not give a word in explanation of the individual symbols the various combinations of which form the complete space group notation.

R. E. GIBBS.

Herpetology: Popular and Systematic

(1) Reptiles of the World:
the Crocodilians, Lizards, Snakes, Turtles and Tortoises of the Eastern and Western Hemispheres. By Dr. Raymond L. Ditmars. New revised edition. Pp. xx+321+90 plates. (London: John Lane, The Bodley Head, Ltd., 1933.) 18*s*. net.

(2) A Monograph of the Frogs of the Family Microhylidae
By H. W. Parker. Pp. viii+208. (London: British Museum (Natural History), 1934.) 15*s*.

(1) THIS well-known book has long been recognised as a standard work on reptile life, and the several reprints which have appeared since its first publication in 1910 testify to its wide popularity and usefulness. In the preface of the revised edition, the author once more expresses the hope that the book will be "everywhere in accord with the latest results of the scientific study of the subject". However, the new edition contains very little new information, and recent herpetological literature is not well covered. Thus, in treating of the Opisthoglyph snakes, the author speaks of "the absence of records to show what their venom is capable of doing", though Fitzsimons (1919) has recorded the potency of Boomslang venom. Besides being dangerously poisonous to man, this is a familiar and abundant South African species which might well have been mentioned here.

It is a source of disappointment to find that the author's experiences in the field, and his unique observations on the feeding, care and treatment of reptiles in captivity during the twenty-three years since the first edition appeared, have not found a place in the new edition of his work. While the nomenclature has been brought up to date, the revision is unfortunately inconsistent: it will be misleading to readers unfamiliar with the subject to see the same genus mentioned within a few lines of print under the two names *Glauconia* and *Leptotyphlops*, while the largest genus of skinks is inconsistently referred to as *Lygosoma* and *Leiolopisma* in different parts of the book.

Misprints appear to be few: the following should be rectified in the next edition: "comical", p. 29 (conical); "Abamidae", p. 33 (Agamidae).

The revision might well have been extended to correct a number of awkward expressions (such as that on p. 43, where we read: "One generally anticipates an awakening of insect life with the coming of darkness, and he is not disappointed") and grammatical errors (such as the use of "dove" for "dived"). Throughout the book "habitat", a word which normally has an ecological rather than a geographical significance, is incorrectly used for "distribution".

Referring to the parallelism of characteristic genera in the Old World Agamidae and the New World Iguanidae, we do not agree with the author's statement "This in no way relates to adaptation". It is significant that many of these unrelated lizards resemble one another, not only in outward appearance, but also in habits and habitat, and this similarity—as, for example, in the arboreal *Agama atricollis* and *Uraniscodon plica*, the desert-dwelling *Moloch* and *Phrynosoma*, and the cursorial *Liolepis* and *Dipsosaurus*—is probably the result of adaptation to a similar mode of life. It would be interesting to have reliable evidence (which is yet lacking) for the belief, here repeated, that the lateral skin-flaps of the gecko *Ptychozoon homalocephalum* "serve the animal in parachute-like fashion, enabling it to make long, scaling leaps from tree to tree". One function of these flaps is certainly cryptic, in that they tend to eliminate the gecko's shadow, and thus add to the effectiveness of its resemblance to lichen-covered bark.

The shortening of the book by some fifty pages is a doubtful improvement, for it has been made at the expense of the bold type which characterised the earlier edition, and which is here replaced by smaller and less clear print. A fine study of *Varanus komodoensis* appears on the frontispiece: otherwise the illustrations are the same, and the steep-angle photograph of *Natrix natrix* reappears upside-down on plate 38. The plates have now been conveniently collected at the end of the volume, and the printers' rendering of the author's many excellent photographs on a better quality paper is a distinct improvement on earlier editions.

(2) In making this much-needed revision, now published as "A Monograph of the Frogs of the Family Microhylidae", Mr. H. W. Parker has successfully accomplished a difficult task. The work has evidently been prepared with great care, and it comes well up to the high standard which one associates with publications sponsored by the trustees of the British Museum. Embodying as it does the latest ideas on the classification of this group of frogs, it will be welcomed by students of herpetology, for it represents the first complete account of the family written in English since the publication in 1882 of Boulenger's well-kno. "Catalogue of the Batrachia Salientia", which accounts for less than one quarter of the species of the family known to-day.

During the past fifty years, various schemes of classification have been proposed, only to be rendered in turn more or less obsolete by th progress of research and with the accumulatio of fresh material. Earlier classifications we found unsatisfactory because they were base upon characters later shown to be unreliable The author has had access to ample material comprising the large majority of known species, and his classification of the group will be the more valuable on that account.

The introductory section (pp. 1–18) opens with a historical résumé of the family. This is followed by a detailed account of the characters, mainly osteological, to which taxonomic importance is attached. The larval stages (known in relatively few species) are considered in their bearing upon a natural classification of the group. Seven subfamilies are now recognised—an arrangement which expresses the inter-relationships of the various genera, and which, the author tells us, "has the merit of according with the facts of geography as well as of morphology". The present distribution of the family is discussed in relation to its past distribution in time and space, of which, in the entire absence of fossils, our knowledge must largely rest upon a foundation of conjecture rather than of fact.

The second and main section of the work (pp. 19–200) contains the systematic account of the 184 species, which are assembled into forty-three genera. Under each of the latter, the author gives a list of references—the type species being designated—a definition of the genus, and a synopsis of the contained species. For each species, there is a synonymy referring to all the more important papers, the locality of the type specimen being given. Following the description, there is a statement of the known distribution, and a list of the specimens (in all, more than 1,600) actually examined by the author, with particulars as to source, date, sex, locality, and the collector's name where this has been traced. A number of clear original text figures and a very complete index add materially to the usefulness of this well-arranged and well-printed volume.

To the systematic herpetologist Mr. Parker's work will be indispensable: but it is to be hoped that the book—providing as it does an excellent and trustworthy means for identification—will also stimulate a wider interest in this large but obscure group of frogs, the habits and life-histories of which are little known.

HUGH B. COTT.

Vitamin B in the Diet of Man

The Vitamin B Requirement of Man

By Prof. George R. Cowgill. (Published for the Institute of Human Relations.) Pp. xix+261+4 plates. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1934.) 18*s*. net.

THE title of this book is so intriguing that all who are interested in nutrition will wish to know how the author has arrived at such a definite assertion, especially in view of the fact that man's requirement for vitamin B cannot be studied by direct experimentation.

Dr. Cowgill has attempted the problem indirectly. He has ascertained the minimum vitamin B requirement of different species of animals (rat, mouse, pigeon, dog) in terms of a special yeast preparation, using animals of widely different weights. His data pointed to the minimum vitamin B requirement being related to some power of the body weight. By trying various values for this power, he found that the figures agreed with the expression vit. $B = K \times Wt.^{5/3}$, and that there was a factor common to all the species. Bringing into account the maximum normal size of the different animals, the expression became vit. $B = 4{\cdot}9 \times W^{0{\cdot}66} \times \frac{W}{W_{max.}}$ and it agreed remarkably with the experimental figures. As $W^{0{\cdot}66}$ may be taken to indicate metabolism, since basal metabolic rate and body surface are functions of the 2/3 power of the body weight, and as from food intake figures Calories $= 1{\cdot}5 \times W^{0{\cdot}66}$, the expression becomes vit. $B = 4{\cdot}9 \times \frac{\text{Cal.}}{1{\cdot}5} \times \frac{W}{W_{max.}}$. Since $W_{max.}$ is a constant, the formula reduces to vit./Cal. $= K \times W$. For man, taking 115 kgm. as the maximum weight, the formula is vit./Cal. $= \frac{3{\cdot}27}{115{,}000} \times W$, or $0{\cdot}0000284\ W$. The vitamin is taken in milligrams of the special preparation and the weight in grams. It should be noted, though not mentioned by Cowgill, that a vitamin/carbohydrate ratio was suggested by Randoin and Simonnet and a vitamin/Calorie ratio by Plimmer, Rosedale and Raymond, who considered that it should have a constant minimal numerical value.

By plotting vit./Cal. ratios as ordinate against weight as abscissa and using the line given by the maximum weight of 115 kgm., a series of ratios are given for different body weights. Reference to the chart shows the vit./Cal. ratios of 1·25, 1·50, 1·75, 2·00 corresponding to weights 40, 50, 60, 70 kgm. respectively. The minimum ratio for a man of 70 kgm. is thus 2·00. Figures near the line are border-line, figures above show sufficiency and below too little vitamin B.

To check the accuracy of the vit./Cal. ratio, Prof. Cowgill has collected together the diets of peoples in various parts of the world which did and did not give rise to beriberi. Beriberi is due to a deficiency of vitamin B in the diet. These diets have been evaluated for their vitamin B content in terms of the special yeast preparation. Foodstuffs had been tested by other workers, some of which had been tried by all the workers and also by Cowgill. It was thus possible to calculate all the figures on the same unit. A useful table of these values is given, and it is possible to recalculate the figures in terms of other units, or the international unit, as a table is shown giving the approximate equivalents of the various units. The vit./Cal. ratio of any diet could thus be determined.

The diets of the sufferers from beriberi had vit./Cal. ratios of 1·74, 1·96 to 2·18, 1·35 and lower values. Diets on which beriberi did not appear had the corresponding ratios of 2·18, 2·26 to 2·46, 1·97, 2·96. These figures agree closely with those shown on the chart. Occasionally there were discrepancies, but on referring to the weight it was found that the weights of the individuals were either above or below the chart line. An examination of a series of diets consumed in the United States showed the vit./Cal. ratios of 2·01–3·39. The value of 2·05 is regarded as borderline for a man of 60–70 kgm.

Though many workers will not agree with Cowgill's method of trying to fix a vitamin B–Calorie ratio as a means of determining the vitamin B requirement of man, yet it must be granted that an analysis of the diets leading to, or preventing, beriberi for their vitamin B content is an essential step. The book gives further details of the occurrence of beriberi since the date of Vedder's book, the diets of the peoples in the beriberi districts and other useful information. A chapter is devoted to other clinical conditions associated with lack of vitamin B. It is hoped that the attention of physicians be directed to the importance of vitamin B to health. It is not correct to believe that there is plenty of vitamin B in the ordinary diet and dismiss it from consideration. The vitamin/Calorie ratio should be checked in cases of enlarged heart, bradycardia and disorders of the digestive tract.

Biochemical Progress

Annual Review of Biochemistry

Edited by James Murray Luck. Vol. 4. Pp. vii + 639. (Stanford University, Calif.: Annual Review of Biochemistry, Ltd., 1935.) 5 dollars.

THE three previous volumes of these reviews have proved of so much value to biochemists that the form of their continuation is a matter of general interest. In no branch of science is there a greater flood of published work, more need of analysis and a better chance of an unexpected discovery illuminating further progress. The subject is essentially fluid, and reviews under stereotyped headings may easily become sterile. Hence the editors have encouraged the policy of analysis of selected papers chosen on account of their intrinsic importance and significance. It is for the reviewers and the readers of reviews to co-operate, the former by selecting and the latter by suggesting subjects which are ripe for comment.

It should be remarked that the three trial years being completed, the enterprise of editing and publishing the "Review" becomes one and the same, and is established as a non-profit earning corporation. It is appropriate to hope that it will receive a generous measure of support from the ever-growing number of British biochemists.

Turning to the recognition of fields of immediate interest, this volume includes reviews on choline and allied compounds by Gaddum, the biochemistry of malignant diseases by Holmes, plant hormones by Thimann. In all, there are twenty-seven reviews by an international assembly of authors.

Enzymes are a subject in which there is annual progress; this time it is reported by J. B. Summer that six enzymes and two zymogens have been isolated in the crystalline state. Enzyme chemistry is becoming more or less identified with protein chemistry, and we are perhaps on the road to clear up some of the facts relating to the higher molecular state of proteins.

The domain of carbohydrates is likewise never without new problems and new discoveries; it is handled by the sympathetic pen of Sir James Irvine, who confines his summary to the more purely chemical developments, leaving for the moment the striking observations connecting polysaccharides with immunological reactions. The synthesis and constitution of ascorbic acid is perhaps enough for one year, but there is much else to chronicle.

As to the proteins and their constituent amino acids dealt with by Edwin J. Cohn, it is noteworthy that progress owes much to physical measurements, particularly X-ray diffraction studies which reveal both the distances between carbon atoms in the chain, and further, the relations between atomic groupings in the peptide and hydrocarbon chains and much else besides. This very important review seeks to set forth principles in terms of which a complete description of behaviour may ultimately emerge.

The sulphur compounds, reviewed by Howard B. Lewis, retain their interest, particularly glutathione with its role as activator or co-enzyme for enzyme activity. The evidence for, and against, the view that the sulphydryl group is a specific stimulus for growth is summarised: it appears to be a promising line of research.

Plant pigments are summarised by R. Kuhn, who has contributed so much to their elucidation. He describes the carotenes with their established formulæ, and shows how the cleavage of the carbon skeleton of a carotinoid with forty carbon atoms yields in theory other natural products, the structure of which depends on the point of cleavage. Four natural pigments are now recognised as provitamin A. The flavins first obtained from milk have been characterised and synthesised; as much pigment has been made from 100 gm. of dimethyl-4-amino-5-methylamino benzene as from 750,000 litres of milk. This shows how advanced is the chemical technique of dealing with minute quantities.

The elucidation of the molecular structure of the alkaloids, particularly morphine and strychnine, is one of the most difficult problems which confronts the chemist. It is one in which he will not admit defeat, and to solve it he tries method after method of attack. The progress is, therefore, steady rather than spectacular; it is appropriately summarised by Robert Robinson.

A new subject for review is that of growth substances in plants, in particular auxin, of which the structural formula has been established. This field may be expected to yield remarkable results in the not too distant future.

Space will not permit of further specific reference, but enough has been said to indicate the utility of the annual reviews and the amazing amount of work which is in progress. The chemist has been accused of war-promoting activities: such are as nought compared with the attempts to understand living tissues which are being made in a thousand and more laboratories.

"Farther, deeper may you read,
Have you sight for things afield."

E. F. A.

Atomic Physics

By Dr. Max Born. Authorised translation from the German edition by Dr. John Dougall. Pp. xii+352. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1935.) 17*s.* 6*d.* net.

IN 1933, Prof. Max Born published in German "Moderne Physik", which has given rise to the present English version by Dr. John Dougall. This book is, however, more than a mere translation, for it has been brought thoroughly up to date so as to include the discovery of new particles and their role in the constitution and disintegration of atomic nuclei. The author has included a clear account of his own views suggesting a higher limit to the possible magnitude of an electromagnetic field, somewhat as the velocity of light appears in physics as the maximum velocity of particles. In this way, Born retains Maxwell's equations and the usual relation between energy and mass, and obtains for the size of the electron $2{\cdot}28 \times 10^{-13}$ cm. and for the absolute field $9{\cdot}18 \times 10^{15}$ E.S.U., but these values may be modified by the effect of spin, which, as he points out, has not yet been satisfactorily dealt with as a real electromagnetic angular momentum from the point of view of his theory. Incidentally, there is on page 46 and appendix vii an ingenious and simple derivation of the Einstein formula $E = mc^2$.

This book gives a comprehensive review of modern atomic physics in 256 pages, while the proofs of formulæ are placed in 31 appendixes (87 pages). The author is careful to point out the limitations and defects of modern theories no less than to set forth their brilliant successes, while he attempts to erect signposts for guidance in future advances.

The relations between the two types of statistics and the symmetric and antisymmetric wave forms are stated with exceptional clearness. The necessarily elusive character of modern views is sufficiently indicated. A wave packet should be almost evanescent, and yet it is possible to hold in the hand a large pitchblende crystal and to state it has remained almost in its present form for 1,400 million years. The microscopic universe is as indeterminate as an animal in the Zoo, when you do not know in which cage it may be, and, if found, the animal dashes off to hide as soon as you try and look at it. Sometimes, however, it leaves a trail, sometimes flashes a light.

A. S. EVE.

The Pineapple

By Maxwell O. Johnson. Pp. xii+306. (Honolulu: Paradise of the Pacific Press, 1935.) 5 dollars.

THE pineapple industry of Hawaii has been built up within the last forty years. In 1896 a large consignment of plants of the 'Smooth Cayenne' variety was imported from Queensland and formed the foundation of the present industry. A few thousand canned fruit were produced by 1902, and by 1913 the production had risen to 2,600,000 cases. It has now reached the enormous total of 12,000,000 cases, or about 300,000,000 marketable fruit per annum.

In 1916 cultivation was confined to the uplands, as plants grown on the lower lands suffered from what was known as 'pineapple yellows'. The discovery by the author that this was due to lack of available iron in the soil, and that the disease could be cured by spraying with iron sulphate, meant an immediate and rapid expansion of the area under pineapples. Other ailments from which the crop suffered have been investigated and largely controlled.

The author of this book, and other technical workers, have been mainly responsible for the maintenance and development of this industry, and there can scarcely be anyone more competent to write a study which deals so admirably with all aspects of cultivation of this crop and which describes in detail the methods adopted to control disease. The book closes with an account of the marketing of both the fresh and the preserved fruit.

This work not only deals with the pineapple in Hawaii but also summarises the experience gained in other countries, many of which have been visited by the author in his search for knowledge of the crop.

Mid-Ice: the Story of the Wegener Expedition to Greenland

By Johannes Georgi. Translation (revised and supplemented by the Author) by F. H. Lyon. Pp. xiv+247+24 plates. (London: Kegan Paul and Co., Ltd., 1934.) 12*s.* 6*d.* net.

THE Wegener expedition to Greenland in 1930 planned to maintain a meteorological observatory on the ice sheet in the heart of the country. The volume before us is the story of how this task was achieved. Transport from the coast, some two hundred and fifty miles away, broke down, but the work at the central station was not interrupted although the party, and at times Dr. Georgi alone, lived in a hole in the ice. They had food, but little else. Here in diary form is the frank record of life under those dreary conditions. Wegener himself lost his life on a journey to the coast; but the expedition has important results. Few of these, however, are given in this general volume, which has its interest chiefly in showing what man can endure in the cause of scientific discovery.

China's Geographic Foundations: a Survey of the Land and its Peoples

By Dr. G. B. Cressey. Pp. xvii+436. (New York and London: McGraw-Hill Book Co., Inc., 1934.) 24*s.* net.

THE author knows China from end to end, and has produced a valuable book, which should be studied by every student of geography. So much that is written on China is solely political and superficial; but this study strikes down to basic physical conditions, and from position, relief, soil and climate builds up an explanation of Chinese life and activities. Problems of climate and their relation to agriculture are especially well treated. Manchuria and the outer dependencies of China are included. There are numerous clear maps, many excellent illustrations and copious bibliographies. Prof. Cressey has succeeded in writing geography without dullness, and given a survey of lasting value.

Centenary of the Landing of Charles Darwin on the Galapagos Islands

CHARLES DARWIN landed on the Galapagos Islands on September 16, 1835, and spent about five weeks observing and collecting in the archipelago. His observations, especially on the differences presented by the finches and the giant tortoises found on the different islands, provided the basis for the new line of thought which resulted in the hypothesis of the "Origin of Species".

The committee of Section D (Zoology) of the British Association arranged that the centenary of his landing should be commemorated by a series of communications occupying the afternoon meeting at Norwich on September 6.

Sir Edward Poulton, in an opening address, reminded the audience that Darwin sailed in the *Beagle* in December, 1831, when he was not yet twenty-three years of age. Nearly four years later the ship reached the Galapagos Islands, and Darwin observed how every kind of animal, and particularly the finches and the giant tortoises, on each island differed slightly from those on the other islands. He realised that these observations, if well founded, "would undermine the stability of species"; that, in fact, he must abandon the idea of the separate creation of species, though he was entirely unable to account for their origin. The solution of this problem became the great work of his life.

Sir Edward Poulton divided the past century of evolutionary thought into three periods. First came a time of inactivity for nearly everyone except Darwin, who began his first notebook on evolution in 1837. In the following year he read Malthus "On Population", and "in a sudden flash of insight" came the idea of natural selection as the great motive force of evolutionary progress, and on this he worked and pondered for twenty years. The second period opened in June 1858, when Darwin received Wallace's letter and manuscript, written at Ternate, in the Moluccas, which showed that Wallace had reached an identical position. Their views were placed before the Linnean Society on July 8, and Darwin's "Origin of Species" was published in the following year. The third period began with the rediscovery in 1900 of the work of Mendel, at first supposed by many to be opposed to Darwinism, but which threw new light on inheritance, led to many new facts consistent with natural selection and solved the difficulty, which Darwin had felt to be the greatest of all—the supposed "swamping effect of intercrossing". Sir Edward Poulton reaffirmed his strong belief in the value of the theory of natural selection.

Prof. J. H. Ashworth gave an account of Charles Darwin as a student in Edinburgh from October, 1825 until April, 1827. The sources of information on this period were the minute book of the Plinian Society of Natural History of the University of Edinburgh, of which Darwin was a member during his second academic session, and a note-book begun by Darwin in March, 1827. The minute book is of interest as showing the range of subjects discussed in the students' natural history society in Edinburgh one hundred years ago, and as containing the record of Darwin's presentation to the Society on March 27, 1827 of his original observations on the 'ova', which were in fact larvae, of the polyzoan *Flustra* and on the 'ovum' or egg-case of the marine leech *Pontobdella muricata*. Darwin's observations on these two subjects occupy four and a half pages in his notebook, which also contains notes on other marine animals, which he collected in the Firth of Forth and examined in Edinburgh.

Prof. Ashworth referred to other papers found among Darwin's Edinburgh notes, and to a few of Darwin's friends, of whom the most important were Robert Grant, a very energetic collector and investigator of sponges and other marine invertebrates, who left Edinburgh in 1827 to be the first professor of zoology in University College, London, and William Macgillivray, then assistant keeper of the Natural History Museum of the University of Edinburgh, who was well known for his special knowledge of birds. Prof. Ashworth concluded that in Edinburgh Darwin laid the foundation of his knowledge of the science of natural history.

Prof. G. D. Hale Carpenter, who was asked to speak on Darwin and entomology, pointed out that Darwin's early interest in entomology was overshadowed in later years as other subjects became more absorbing. He proceeded to refer to one aspect of entomology which has been much aided by the principle of natural selection, namely, the study of the coloration of insects. Prof. Carpenter held that concealing coloration, warning coloration and mimicry could all be accounted for by natural selection, and not by any other explanation which has yet been brought forward. Before Darwin's day, conspicuousness could not be satisfactorily explained except by appeals to anthropocentric ideas or terminology.

Prof. E. W. MacBride said that if Darwin had produced no other book than his journal of researches during the voyage round the world of H.M.S. *Beagle*, he would have shown himself to be one of the finest naturalists that ever lived, and his description in this work of the Galapagos Islands and of their fauna is a most masterly production. Prof. MacBride proceeded to refer to the giant tortoises, the lizards and the birds, and said that Darwin was at an utter loss to account for the prodigality of creative power which had resulted in the different islands having distinct species of tortoises and birds. Later Darwin applied his theory of natural selection to the explanation of the occurrence of the variety of species in the different islands. Prof. MacBride expressed his strong dissent from this explanation and from Sir Edward Poulton's views, and concluded by stating that in his opinion the ultimate cause of difference in species is difference in habits and in reaction.

Mr. H. W. Parker recalled Darwin's statement that the reptiles of the Galapagos gave "the most striking character to the zoology of these islands". During the last century, the number of species of reptiles was found to be greater than Darwin had realised, but the increased knowledge emphasises what he considered "by far the most remarkable feature in the natural history of this archipelago—that the different islands to a considerable extent are inhabited by a different set of beings". Mr. Parker, in giving an account of the present distribution of the reptiles in the islands, stated that of the fourteen species of giant tortoises, three are probably extinct and most of the others exceedingly rare. The curious marine lizards (*Amblyrhynchus*) and the land lizards (*Conolophus*) are also in grave danger of extermination. Man has been the principal destructive agent in the past, but the future of all species, large and small, is jeopardised by the presence on the islands of introduced pigs, dogs, rats and cats which have run wild. That the remnants of the fauna are in imminent danger has been realised by the Government of Ecuador, which has passed decrees proclaiming certain of the islands as 'asilos reservados', and also giving protection to all the interesting indigenous species throughout the archipelago. Mr. Parker urged that only international co-operation could make this legislation effective, and that the British Association should initiate action to this end.

An Early Stone Age Culture of America

REFERENCE to the discovery of 'Folsom points' and to 'Folsom man' in the archæological literature of the United States from time to time within the last decade has given rise to an expectation that it might be possible, within a comparatively short time, to construct some sure and certain foundation for the claim to a relatively high antiquity for early man in America, which has often been advanced, but never satisfactorily substantiated. Since the Folsom point was first recognised in 1927 as an early and specific stone age industry of North America, occurring on occasion in association with a presumedly early fauna, later discoveries and further study of its characteristics and distribution have given clearer definition to the archæological problem and indicated the direction of intensive search for the geological and palæontological data upon which the solution of the chronological problem ultimately will depend.

Passing reference has been made in the columns of NATURE from time to time to the discovery of evidence relating to Folsom man. Such evidence was by no means always such as to carry conviction, nor did it give, although the 'point' itself is sufficiently characteristic, any clear impression of a specific cultural phase. Such uncertainties, however, are now to a great extent removed by the recent examination and partial excavation by Frank H. H. Roberts, Jr., archæologist of the Bureau of American Ethnology, of a Folsom midden in a locality now particularised as the Lindenmeier Site, twenty-eight miles north of Fort Collins, in northern Colorado. His report* has not only made important and substantial additions to knowledge of the Folsom culture and technique, but it has also crystallised previous evidence and affords opportunity for review of the data relating to the Folsom culture as a whole.

It may not be out of place to point out that, while it is now possible, thanks to Mr. Roberts's new evidence, to form a fairly clear conception of the Folsom phase of culture, Folsom man is unknown. No human skeletal remains have been discovered in association with Folsom artefacts as yet.

In the light of the evidence from the Lindenmeier Site, as will appear later, there is now justification

* "A Folsom Complex: Preliminary Report on Investigations at the Lindenmeier Site in Northern Colorado". *Smithsonian Misc. Collect.*, **94**, No. 4.

for speaking of a 'Folsom culture' of which the existence previously had been a matter of inference only, from the type of a single class of implement, and of which the picture even yet is not complete in detail. It is the culture of a hunting people closely associated with the bison. A concurrence of evidence, geological, palæontological and archæological, points to the conclusion that not only does it represent an earlier phase in the American cultural sequence than that of the 'Basket-Makers' of the Pueblo area, hitherto regarded as the earliest to appear in the south-west, but also that in the instance of the Folsom implements a case for a quaternary dating has been made out with a closer approach to certainty than in any other culture of the American stone age.

The Folsom point, the characteristic implement of the culture, is of a triangular, or rather leaf-shape, in which the greatest breadth lies between the tip and the middle point of the blade. In size, it varies from 17 mm. to 75 mm. in length, 14 mm. to 32·5 mm. in breadth and 3 mm. to 6 mm. in thickness. A variant form has rather a wider range in size. The material is varied, chalcedony, jasper, chert, quartzite, petrified wood, moss agate, geyserite (rare) and white sandstone, all being recorded.

The indigenous inhabitants of North America have always been essentially a stone-using people. Even the native copper area of Lake Superior developed a chalcolithic rather than a true metal culture. Within living memory, stone implements continued to be made in California in full view of the railway track. In the course of their long history of stone using, the Indians developed many eccentric forms of implement, for which anthropologists, in default of a better understanding, have been content perforce to accept the designation 'ceremonial'; but of all the implements fashioned for practical use, probably none is more distinctive than the 'Folsom point'. Its peculiar characteristic is a longitudinal groove, or channel, running down the middle of the blade, which leaves a ridge on each side parallel with the edge. As the two faces of the typical implement are identical in form, this gives it in section the shape of a double concave. The sides are prolonged at the base to form wings, making the base a semi-circular gap or notch.

The form of the point, obviously the tip of a projectile weapon, either arrow or spear, made it peculiarly liable to fracture. The vast majority of the implements of this type which have been found are broken, only the tip or the butt-end being found. The predominance of the butt-end on the Lindenmeier Site no doubt was due, as Mr. Roberts has suggested, to a practice of retrieving the shaft of the weapon and bringing it back to camp to fit a new point. The purpose of the remarkable channel is unknown, although the groove in the modern bayonet at once suggests an analogy.

A brief reference to the course of research which has led up to Mr. Roberts's investigation, will not be out of place, especially as, in so far as it relates to the question of distribution, it has a bearing on the interpretation of the evidence relating to the Folsom culture which needs further elucidation.

As already mentioned, the specific character of the Folsom point was established in 1927. Before that date, and indeed so far back as 1897, the peculiar features of the implement had been noted; but as the specimens were mostly surface finds, their significance had not been appreciated. In 1925, the attention of J. D. Figgins, director of the Colorado Museum of Natural History, was directed to a bone deposit on the upper sources of the Cimmaron River near Folsom, New Mexico. Investigations in the following year brought to light evidence which seemed to demonstrate beyond question the definite association of stone artefacts and an extinct bison. Additional 'points' were found in 1927 by investigators working on behalf of the Colorado Museum, and Dr. Barnum Brown of the American Museum of Natural History found one specimen still embedded in the matrix between two of the ribs of an animal skeleton, where it still remains on exhibition in the Colorado Museum. It was seen *in situ* by Dr. A. V. Kidder, as well as by Mr. Roberts. It was then agreed that not only could the association not be questioned, but also that the points were totally different from the ordinary types of stone implement hitherto found in the south-west.

In the following year (1928), joint operations by the American Museum of Natural History and the Colorado Museum under Dr. Barnum Brown and Dr. Clark Wissler were made the occasion of an informal conference of geologists, palæontologists and archæologists, who arrived at the generally accepted conclusion that the Folsom find indicated an earlier appearance for man in the south-west than had hitherto been allowed. It was under date of this year that the first account of the Folsom point appeared in Europe in an article by E. B. Renaud on the antiquity of man in North America in *L'Anthropologie*, 38, 23–49.

Of later activity in the study of the problem and search for further evidence, mention may be made of the work in New Mexico of E. B. Howard, of the Pennsylvania University Museum, and of Prof. E. B. Renaud, of the University of Denver, and his students in their archæological survey of Colorado and Nebraska. The former has found in a cave in the Guadalupe Mountains in the south-eastern part of New Mexico a Folsom point in conjunction with musk ox and an animal of the

musk ox group. These occurred in a stratum underlying a level containing Basket Maker material. This find thus established definitely the priority of the Folsom culture. At the same time, the musk ox being a cold-climate animal, it is generally considered to be evidence of the contemporaneity of Folsom man with an Ice Age fauna. Further investigations by Mr. Howard near Clovis, New Mexico, also point to the co-existence of Folsom man and an extinct fauna; but here the evidence is considered open to question, and until it has been published in fuller detail, must be regarded as still *sub judice*.

On the general question of the quaternary age of the Folsom implements and the associated extinct fauna, opinion is at present divided. While some would see in this association evidence for the existence of man in America in late Pleistocene times, others maintain that it points rather to a late survival of Ice-Age animals into recent periods, and that there is no evidence that man was actually present in America in the Ice Age.

Of Prof. Renaud's investigations, what must be regarded as the most important outcome to date is a distinction in the character of the culture which he recently claims to have established. This differentiates the Yuma point from the Folsom point. The former, on the basis of typology, he considers to be older than the Folsom. The two occur in association on many sites as surface finds, and their relative antiquity is still under discussion.

We may now turn to Mr. Roberts's investigations on the Lindenmeier Site, which must be regarded as one of the most important contributions of recent years to prehistoric archæology in America.

The Lindenmeier Site was first discovered by Judge C. C. Coffin and his son, A. L. Coffin, in 1924. From it they collected some 83 points or portions of points, as well as about the same number of other artefacts. They were not, however, then aware of the significance of the former; and it was not until 1930 that they were informed by Prof. E. B. Renaud that they were Folsom points. Further surface finds were made afterwards; but it was only in 1934, when the site was examined by Mr. Roberts, that any intensive investigation was attempted. The finds by members of the Coffin family had been made in a restricted area, some 70 yards by 150 yards in extent; but the point at which Mr. Roberts's excavations were carried out lies apart from this area, and is situated in the side of a ravine or gully about a quarter of a mile away. Here an undisturbed and intact layer of midden material was found at about 14 ft. below present ground-level and about 12 ft. above the bed of the gully. This was partially excavated in October and part of November, 1934; and it is hoped to carry the work further on a future occasion. The midden lies at the deepest point of an implementiferous area lying between the edge of the gully and a terrace, and covering ground approximately 250 yards by 200 yards. The objects of bone and stone are found just above a clay stratum in a layer six inches to one foot in thickness. Except at the midden, where was the main concentration of archæological material, finds over this area are in the nature of chance accumulations.

Of the actual finds, the Folsom points both whole and fractured, as well as flakes and specimens spoiled in making, have afforded Mr. Roberts material for pertinent suggestions as to the obscure technique of manufacture upon which it is not possible to touch here. A large proportion of the other artefacts are scrapers, of which there are several varieties. Some show minute and careful chipping, others are rough and crude. Most belong to the curved end, or 'thumb-nail' type. Of the side-scrapers some are almost paper-like in their thinness. While there is no definite knowledge as to the uses to which some of these scrapers, such as the turtleback and the side scraper, were put, they would serve for dressing skins as well as for knives, gouges, adzes or abrading tools. One of the most interesting types is a graver, an implement familiar in European archæology; but no other evidence is to hand of the practice of the graver's art by Folsom man. Most of these gravers are fortuitous flakes, which have been modified by chipping a small sharp point on one side or end. Some, however, are more definitely shaped. A number of specimens among the implements are classified as knives. The best are carefully chipped blades, which exhibit typical Folsom characteristics in their fluted faces and the marginal retouch. Several of them are made from the channel flakes resulting from the manufacture of points. Among other implements are blades and choppers. Miscellaneous objects include pieces of sandstone showing signs of use—there is no material of this character in the neighbourhood—pieces of hæmatite, smooth and striated from rubbing (a good indication that they supplied pigment material) nodules with battered ends (no doubt hammers) and a number of fragments of bone, which had served as tools.

Most of the bone material was scrappy. Bison, fox, rabbit and wolf have been identified. It is noted as a matter of considerable interest that the bison is identical with the two extinct forms found at Folsom, *Stelabison occidentalis taylori* and *Bison oliverhayi*.

It will be seen that the excavations which have been carried out by Mr. Roberts on the Lindenmeier Site have extended very considerably knowledge of this stone-using, hunting culture, in which

future excavation may well fill in further detail. One point remains to be mentioned. On determination of the specific character of the Folsom point and the advancement of its claim to a high antiquity, attention was directed, as already mentioned, to the fact that it was already known, in one instance at least, having received the name of the "Seneca River point". It was shown to have a wide distribution—from southern Canada to the Gulf of Mexico and from the Rockies to the Atlantic. Further study, however, has demonstrated that the true Folsom points are confined to the High Plains on the eastern slope of the Rockies, while the more widely distributed point is a larger, more generalised form, centring notably in the Finger Lakes section of New York State, in Ohio, Tennessee and southern Virginia. The affiliation and the chronological and distributional relation of the two forms are problems which are now being made the subject of study by Mr. Roberts.

Until the typological and chronological relations of the two forms of point are established with some degree of precision, no finality in the interpretation of the archæological evidence is attainable. Tentatively, however, it may be pointed out that the evident antiquity and the known distribution of the true Folsom point are consistent with the view that it is a specialised form developed by the people who, it has been suggested, penetrated to the south-west in the period of transition at the close of the Ice Age along a corridor on the eastern slopes of the Rockies. It will be interesting to see if the researches in Siberian archæology, upon which Mr. E. B. Howard is to engage, produce any typological evidence of an Asiatic ancestry for this remarkable American type of implement.

The Percy Sladen Expedition to Lake Huleh

HULEH is a shallow lake lying in the northern end of the Jordan Valley, where it extends towards Mount Hermon. The sides of this valley are formed here by two parallel ranges of mountains, but at the south end of the lake the valley is closed by low hills except where the Jordan has cut a deep gorge into Lake Tiberias, the fall to which is 600 feet. The actual lake is approximately five miles long by three across, and is roughly pear-shaped, with its broad end to the north. Its maximal depths are 10–12 feet, but its greater part is not more than 4–5 feet. On its east side the mountains, which are basaltic, commence their rise close to the lake, and the shore is rocky, much large material being carried down the numerous water-courses. On the west side, a broad plain extends out from the lake, for the strong winter torrents have brought down quantities of gravel, which form spits projecting into the lake. Over most of the central area, the bottom of the lake is of soft grey mud, which is largely populated by plants of *Potamogeton*. At the extreme south, there is a small area where *Phragmites* dominates, and this also grows on the eastern side in isolated patches. On both sides of the lake there are numerous springs, and some cold patches in the lake are supposed to mark further effluents.

The lake is bounded on its northern side by a large swamp, through which the Jordan flows as a swift stream, even in the dry season. The swamp begins as a band of floating lilies (*Nuphar*) across its north end, extending down each side for half a mile. On the inside of the lilies, the plant succession is at present being studied. The swamp is not homogeneous in structure, and its most striking feature is the papyrus, which over large areas is the dominant plant form. Through it, progression is only possible along waterways, which are kept open by the Arabs, who use it for many purposes. The swamp consists of a mass of roots, much matted and bound together with plant debris in various stages of decomposition. The roots appear to be floating in the water, and it is easy to sink waist deep through masses of debris, where the papyrus is not too thick. At various places clear pools are found, these apparently due to springs. At the sides of the swamp the land is being reclaimed by Arabs for the planting of maize and millet.

The channel of the Jordan runs down the middle of the northern swamp, where heavier silt has been deposited during the floods of the rainy season. Local observations suggest that the swamp is extending southwards and encroaching on the lake, almost as if pushed by the processes of reclamation on its shores. One of the most striking features of the lake is the large quantity of fine silt brought down by the Jordan, when irrigation is occurring further up the valley. It is of a light grey colour, and quite different from the mud formed by plant decomposition. It is deposited generally over the lake, and forms in addition a broad bar across its northern end.

The rights over the lake have recently been purchased by the Palestine Land Development Co. from the Arab owners. The company has employed engineers to estimate the cost of the drainage of the lake and swamp, and is now selling it upon these estimates. Several interested companies are employing their own engineers to check these. Up to the present, no work has been commenced, but it is anticipated that the drainage, which is a simple question, will be completed in 1936 or the following year.

The biological survey of Lake Huleh is in charge of Mr. Roger Washbourn with a botanist, both from the University of Birmingham. The lake is interesting mainly in comparison with Lake Tiberias and other parts of the Rift Valley in Palestine and East Africa. The presence of animals of African affinity was shown by Annandale in 1916, and the biologists are largely concerned with investigating the fauna and flora before the lake ceases to exist. In addition, Huleh lies near the southern boundary of several palæarctic species. The ecology also of a lake with a papyrus swamp in this latitude should prove interesting. Having these objects in view, the zoological part of the work is largely the collection of animals from the varied habitats that the lake and swamp present. To define these accurately, the physical and chemical conditions are being studied, and these are, of course, a prime factor in governing the plankton. The botanist is fully occupied with his study of the swamp and the interrelations of the plants in their different habitats. The difficulty of transport is considerable—and the lake is fever-stricken—but it is hoped that an impression will be secured of the plant and animal life of an area which will soon have ceased to exist.

The Chemotherapy of Malaria*

QUININE was discovered by Pelletier and Caventou in 1820 and was promptly manufactured in France and England in quantities sufficient to permit of its use in the treatment of malaria, in place of crude cinchona bark. This was an early and unconscious application of the principle upon which Ehrlich was to found chemotherapy ninety years later. By that time, thanks to the labours of Hesse, Skraup, Köenigs, von Miller and Rohde and Rabe, constitutional formulæ had been assigned to quinine and the other cinchona alkaloids, which Rabe and his collaborators confirmed in a series of researches culminating in the complete synthesis of dihydroquinine and dihydroquinidine in 1931. Partial syntheses had been effected some years earlier and the methods employed had been extended to the preparation of products allied to the cinchona alkaloids in type, but of simpler structure. In 1891 Grimaux and Arnaud prepared from cupreine a series of homologues of quinine, one of which, ethylcupreine, was tried clinically and found to be somewhat more active than quinine, and this first French experiment in the production of 'modified cinchona alkaloids' led to the preparation of many other substances of this type.

Chemists had in fact accumulated a mass of possible anti-malarials, the therapeutic value of which there was no practical means of testing. This want was supplied when Roehl devised his technique of testing such drugs in bird malaria, using canaries for this purpose. Of the various 'leads' then available for the synthesis of new anti-malarials, Prof. Schulemann and his co-workers, Schönhöfer and Wingler, selected methylene blue, which had been shown to have some action in malaria, and from this starting point they evolved plasmoquine in 1924. This was followed by atebrin, discovered by Mauss and Mietzsch in 1930.

These two drugs have one feature in common, a dialkylaminoalkylamino-side-chain, -NH-CHMe-CH_2-CH_2-CH_2-NEt_2, attached at position 8 in 6-methoxyquinoline, in the case of plasmoquine, and at position 5 in 2-chloro-7-methoxyacridine, in the case of atebrin; but as acridine is quinoline with a benzene ring fused on, both drugs can be regarded as derived from 6-methoxyquinoline, a characteristic they share with quinine, which, however, has a different and more complex side-chain. Plasmoquine acts preferentially on the sexual forms (crescents or gametocytes) and atebrin and quinine on the asexual forms (schizonts) of the malaria parasite. Their respective actions in the various types of malaria is not as clear-cut as this brief description implies, but it is permissible now to divide anti-malarial drugs into 'anti-gametocyte', represented by plasmoquine and its allies, and 'anti-schizont', of which quinine and atebrin are types.

These discoveries have led to great activity in the synthesis of such drugs in Great Britain, France, Russia and elsewhere, and Prof. Robinson gave an account of the reactions used in the

* Based on a discussion, introduced by Col. S. P. James, in Section B (Chemistry) of the British Association meeting at Norwich on September 9. Other contributors to the discussion were Prof. W. Schulemann, Prof. R. Robinson, Dr. P. Tate (with Prof. Keilin and Miss M. Vincent), Dr. T. A. Henry, Sir Rickard Christophers and Prof. Warrington Yorke.

preparation of the extensive series of potential anti-malarials made in his laboratory. One of these, in which the side-chain of plasmoquine is replaced by -NH-CH_2-CH_2-CH_2-NH-CH_2-CH_2-CH_2-NH_2, was found to have a chemotherapeutic index 1 : 62 against 1 : 32 for plasmoquine and is, therefore, a promising material for clinical trial. The necessary bird malaria tests on these substances are being made in Prof. Keilin's laboratory at Cambridge by Dr. Tate and Miss Vincent, and the former described the methods used. Inoculation of infected blood provides material for tests on asexual forms of the parasite, and birds infected by bites from mosquitoes are used for tests of activity against gametocytes and sporozoites, and details were given of the results of such investigations of a number of Prof. Robinson's substances.

The bird malaria test has also been applied to a number of other problems. Drs. Buttle and Trevan have shown that the interesting series of alkaloids isolated by Messrs. Goodson and Sharp from ten species of *Alstonia* have no action in bird malaria, and the same is true of the alkaloids of *Picralima klaineana*, though both these drugs have some repute in various tropical countries as remedies for malaria. The same workers made a comparative examination of specially purified specimens of the principal cinchona alkaloids and found that, as an anti-schizont drug in bird malaria, quinine was about twice as active as quinidine or cinchonidine, and possibly five times as active as cinchonine.

These results are of considerable interest in connexion with the use of mixtures of cinchona alkaloids as a cheap substitute for quinine, and justify the action of the Malaria Commission of the League of Nations in providing a standard for such mixtures, which prescribes a minimum content of fifteen per cent of quinine. Much work has also been done, particularly by Giemsa, in assessing the therapeutic value in bird malaria of 'modified cinchona alkaloids'. The results show that, so far, no product of this type is much better than quinine or dihydroquinine; but this work has provided a fund of information as to the influence on anti-malarial activity of modifications in the structure of drugs, which will probably be of great value in the biochemical and biophysical investigations, which are beginning to be made in the hope of ascertaining how and why such drugs exert their specific action. As an example of such work, mention may be made of the paper by Sir Rickard Christophers describing the methods he has used, and some of the results obtained in examining the view that chemotherapeutic effect is a result of some kind of combination between protein substance and the basic side-chains, which are a characteristic feature of effective anti-malarial drugs.

It was particularly appropriate that the discussion should be introduced by Col. James, who has had special opportunities for clinical investigation of the new drugs, plasmoquine and atebrin. He provided a careful survey of their value as true causal prophylactics, as means of avoiding relapses and as preventives of spread of the disease, these being the principal characteristics of their action in which they surpass quinine, for they are to be regarded, not as substitutes for this alkaloid, but as additional weapons in anti-malarial campaigns.

Col. James finally expressed the hope that provision would be made in Great Britain for more intensive chemotherapeutical research. On the same point, Prof. Robinson emphasised the need for the closest co-operation between chemists and biologists in work of this kind, and Prof. Warrington Yorke pointed out that, although in a number of cases, such as sleeping sickness and amœbic dysentery, the first useful chemotherapeutical observation had been made by English workers, we had failed to follow up these observations by systematic pharmacological and chemical work, with the result that the countries of the Empire still had to depend largely on imported synthetic drugs.

T. A. H.

Obituary

Mr. J. F. Herd

JAMES FLEMING HERD, senior scientific officer in the Radio Department of the National Physical Laboratory, died on July 22 at the early age of forty-seven years.

Born and educated in Dundee, Herd entered the Post Office, and became a highly skilled officer of the telegraph service. He served in the Royal Flying Corps and Royal Air Force, as an instructor in that part of the service which developed into the Wireless and Electrical School. Retaining the rank of flight lieutenant in the R.A.F. Reserve of Officers, he joined the Meteorological Office as a senior professional assistant, for service at Meteorological Office Radio Station, Aldershot, then engaged in a study of atmospherics in relation to thunderstorm detection. On the formation of the Radio Research Board, that station was taken over by the Department of Scientific and Industrial Research, to which its two scientific officers were seconded, later to become substantive

members of the Department's staff. In the steady growth of the Department's organisation for radio research, he took a rapidly increasing load of responsibility, and the formation of the Radio Department, National Physical Laboratory, in 1933 brought him to the rank of senior scientific officer as officer-in-charge of the Slough Division of the new entity, and as secretary of a number of committees of the Radio Research Board.

Herd's published scientific work falls far short of representing his notable contributions to the progress of fundamental radio research. He submerged his individual interests in the development of that team-working which the Slough Station chose as its method of attack on the complex and varied problems in the pathology of radio communications entrusted to it for study. His contributions to the *Proceedings of the Royal Society*, the *Journal of the Institution of Electrical Engineers* and other papers, and his monograph (jointly with two departmental colleagues) on "The Cathode Ray Oscillograph in Radio Research" give some evidence of his rare gifts as an investigator. His gifts for scientific organisation did much towards the success of the London (1934) meeting of the Union Radio-Scientifique Internationale, in which he took an important part.

Dr. F. C. Shrubsall

DR. FRANK CHARLES SHRUBSALL died at his home in Hampstead on September 25, aged sixty-one years.

He was the only child of a master mariner. Never robust, his health during childhood gave anxiety to his family, and he was taken on several sea voyages. Thus, early in life he came in contact with differing types of men, and this aroused in him that intense interest in the study of mankind which was to shape his whole career.

Shrubsall was educated at Merchant Taylors' School and went up to Clare College, Cambridge, in 1892 with an entrance scholarship. He graduated in 1895 taking first class in the Natural Sciences tripos. He entered St. Bartholomew's Hospital and qualified in medicine in 1900 after a brilliant career as a student. Appointments at St. Bartholomew's and the Brompton Hospital for Chest Diseases gave him much experience in the practice of medicine, and intensified his interest in the study of human types. He proceeded to his M.A. degree at Cambridge in 1899 and took the M.D. in 1903. His remarkable clinical gifts were speedily recognised; he was appointed in 1908 to a Hunterian professorship at the Royal College of Surgeons and elected to the fellowship of the Royal College of Physicians in 1912.

When the British Association met in Cambridge in 1904, Shrubsall read a paper in Section H (Anthropology) on the influence of selection by disease on the constitution of city populations. This paper at once established his position among British anthropologists. He became a secretary of Section H and for eighteen years continued to hold this onerous post. During this period, he contributed many articles to the Section of original and important character and did an immense amount of work on research committees.

The opportunities for continued research held out by the work of the school medical service attracted him, and in January 1909 he was induced to enter the service of the London County Council. Here he found immediate work to hand in the collating and analysis of an immense amount of raw material in the shape of physical measurements which had been collected. As the result of the growth of the work of the school medical service, Shrubsall found himself in 1912 attached to the headquarters staff in charge of the special school division. Thus began his association with problems of mental deficiency and juvenile delinquency, matters in which he was destined to become acknowledged the foremost expert in the country. Increasing pressure of public work compelled him to relinquish his secretaryship of Section H in 1923, and he was elected president of the Section for the Toronto meeting in 1924. He took as the subject of his presidential address "Health and Physique Throughout the Ages".

At the time of his death, Shrubsall was a senior medical officer of the London County Council in charge of a section which included special and reformatory schools, mental deficiency, care of the blind, and medical examination of employees.

The value of Shrubsall's services to British anthropology and of his pioneer work in the sphere of public health, particularly that associated with the elucidation of the problems of mental deficiency and juvenile delinquency, cannot be too highly estimated. He was a man of great generosity and kindness of character, and was greatly beloved by all his co-workers in every sphere. C. J. T.

WE regret to announce the recent death of Baron Léon Frédéricq, emeritus professor of physiology at the University of Liège, at the age of eighty-four years. He was born in 1851 at Ghent, where he became doctor in natural science and medicine in 1871. After studying experimental methods in several foreign laboratories he became assistant in the Department of Physiology and Comparative Anatomy at the University of Ghent, where he carried out investigations on the presence of fibrinogen in the blood plasma. In 1879 he succeeded Theodor Schwann at Liège in the chair of physiology, which he held for more than forty years, during which he carried out important researches on the physiology of circulation, respiration and the nervous system. He was the author of a standard treatise on physiology and a handbook of technique and demonstrations in general and special physiology. At the beginning of the century he was the co-founder with Paul Héger of the *Archives internationales de physiologie*. He also founded a biological station for botanists and zoologists. Frédéricq was a corresponding member of the Institut de France, commander of the Legion of Honour and of the Crown of Italy and fellow of the Physiological Society of London, in addition to many other distinctions.

News and Views

Sir John Flett and the Geological Survey

ON October 1 Sir John Flett retired from the directorship of the Geological Survey and Museum. He joined the Survey in 1901, in 1903 he was appointed petrographer, and in 1911 he succeeded Dr. John Horne as assistant director for Scotland. On the retirement of Sir Aubrey Strahan in 1920, he was made director. He took over his new duties at a moment when several important changes had been introduced; the Committee of Advice on the Geological Survey, which had reported to the Board of Education since Sir Jethro Teall's induction to office, now gave place to the Geological Survey Board, reporting to the Lords of the Committee of the Privy Council for Scientific and Industrial Research; at the same time there was a considerable increase in the scientific staff. With characteristic energy, Sir John Flett began at once to make full use of the improved conditions: one of the first steps was the establishment of three branch offices in coal-field centres, which proved of great value in permitting closer contacts with the industry.

DURING Sir John Flett's directorship, not only has steady progress been made with the primary 6-inch survey, the re-survey of economically important areas, and the provision of colour-printed 1-inch maps, but also there has been marked improvement in the production and style of reproduction, both of maps and memoirs. Other departments of the Survey's activity—the investigation of underground water supplies, recording of boreholes, photography of geological subjects for educational and record purposes, the study of geophysical methods of surveying—have been vigorously stimulated, and useful collaboration has been set up with other bodies in relation to research upon soils, coal and building stones. Sir John's single-minded devotion to the work of the Survey and Museum and to the needs of the public, backed by a keen and able staff, achieved a fitting culmination with the opening of the new Museum of Practical Geology and Survey offices in South Kensington last July.

As recorded in NATURE of July 20, p. 96, Dr. Bernard Smith has been appointed to succeed Sir John Flett as director of the Geological Survey of Great Britain. It is now announced that Mr. Henry Dewey has been appointed to succeed Dr. Bernard Smith as assistant director (England and Wales). Mr. C. E. N. Bromehead, district geologist in York, will shortly take charge of the London District, now vacated by Mr. Dewey. Mr. T. H. Whitehead has been promoted district geologist, and will take over the Survey Office in York upon Mr. Bromehead's withdrawal to London. Dr. J. Phemister has been appointed petrographer in succession to the late Dr. H. H. Thomas.

Faraday's Eyesight and the Blind Spot

UNDER the heading "Science News a Century Ago" a paragraph headed "Faraday's Eyesight" appeared in NATURE of January 12, p. 77. The note referred to an entry in Faraday's "Diary" of date January 15, 1835, in which Faraday stated he had noticed "a slight obscurity of the sight of my left eye". Dr. Frank Marsh, writing from the Pathological Laboratory, c/o Anglo-Iranian Oil Co., Ltd., Masjid-i-Sulieman, via Ahwaz, South Iran, suggests that the quotation in NATURE indicates that "Faraday had discovered his 'blind spot', that is, the optic disc, the place of exit of the optic fibres from the retina, which exists in the retina of every normal person". We have consulted a leading authority on ophthalmology upon Dr. Marsh's suggestion, but he thinks that the explanation of the blur in Faraday's vision as being due to his blind spot is not satisfactory for several reasons. Faraday describes it as a "slight obscurity of the sight", that is, it was a definite blur—in ophthalmological phrase, a *positive* scotoma. The blind spot causes a hiatus in vision, but no positive blur; in other words, causes a *negative* scotoma. Apparently the blur was first noticed when Faraday used both eyes in reading, though it is not definitely stated that the right eye was open. If both eyes were being used, the blind spot would not be noticed in reading. Moreover, the size of the scotoma ("about half an inch in diameter") does not correspond with the visual angle subtended at the nodal point of the eye by the normal blind spot. Faraday's description is meticulously accurate, as one would expect from him, and it is unlikely that he would write "to the right and below the axis of the eye" if the true projection were to the left, as would be the case for the blind spot. It is probable that Faraday had a temporary retinal lesion, possibly a small retinal hæmorrhage, and that this accounted for the obscurity he described. In concluding his letter, Dr. Marsh asks whether Faraday's entry was "the earliest reference to observations on the physiological 'blind spot' ". It was certainly not; for in the second volume of the *Philosophical Transactions* it is recorded that Mariotte demonstrated the blind spot to the Royal Society before King Charles II in 1668.

A Science News Service in London

OF recent years the desirability of establishing a closer relationship than exists at present between the very different realms of science and the newspaper press has been realised by an increasing number of leaders in both; and a year ago attention was again directed to the movement towards a British Science News Service by Sir Richard Gregory, who made "Science in the Public Press" the subject of his presidential address to the Association of Special Libraries and Information Bureaux. The formation

of a British Science Service, either as an independent venture or as a London bureau of Science Service of the United States, had long been desired by the director of Science Service, Mr. Watson Davis, and after a necessary period of preliminary discussion and experiment an organisation in the second form has recently been opened at 102–5 Shoe Lane, London, E.C.4, under the direction of Mr. Donald Caley. About twenty representatives of different departments of pure and applied science, including Sir F. G. Hopkins, president of the Royal Society, have consented individually to act in consultative capacities in connexion with this London organisation. The co-operation of scientific workers with the new venture is invited, by supplying information relating to researches on which they are engaged (such information to be treated as confidential when and for as long as desired); sending advance proofs of original communications to scientific journals which they edit or control, or regular copies of the journals, which will invariably be mentioned in newspaper summaries; and to make to Mr. Donald Caley any suggestions which may help him to increase the scope and usefulness of the organisation.

Cultural History in Nebraska

In another column of this issue (see p. 555) there appears a brief summary of certain conclusions as to cultural sequences in Nebraska, United States, which have emerged as a result of a review of the archæology of that State by Mr. W. D. Strong. It does less than justice to a record of remarkable interest. Among the numerous investigations of recent date, to which Mr. Strong refers, is that of Signal Butte, a stratified site examined by himself, on which evidence of three distinct cultures is to be observed. The levels in which these are found are separated from one another by deposits of Æolian origin, the whole series being superimposed upon sands, which Mr. Strong himself holds to be waterborne and of Pleistocene age. The level of the earliest human occupation is immediately superimposed on these sands. The interpretation of the deposits in terms of climatic variations, based on a correlation with data from other sources, postulates for the whole series, beginning with the period of earliest human occupation, a period of 7,000–10,000 years. Further, this is the only site as yet discovered in America on which stratification gives a clue to the progressive development of type implements of stone in chronological succession. No less interesting and revolutionary in its geographical, archæological and historical implications is a discovery, which hitherto has escaped the attention of archæologists, that while there was a hunting culture on the plains dependent on the bison, in the earliest and in the latest phase of aboriginal existence until it was swept away by Caucasic culture, there intervened between early and recent hunters a semi-horticultural mode of life, akin to that of the Eastern Woodland type, which was forced back to the Missouri with the coming of the horse. This carries with it implications, fully elaborated by Mr. Strong, which necessitate a modification of current views on geographic controls in the Plains area.

Primitive Traits in Amerindian Skulls

It is now generally accepted that no skeletal remains of the genus *Homo* other than those of 'modern' man have hitherto been found on the American continent. Since the arguments put forward by Ameghino early in the present century in support of the primitive character and high antiquity of the skulls he had found in South America were shown by Dr. Aleš Hrdlička to be untenable, it has been claimed from time to time that human remains exhibiting characters other than those of *Homo sapiens* have been discovered; but invariably closer examination of the evidence has failed to support this interpretation. One of the latest discoveries of this nature is that of a fragment of a skull found by Dr. Earl H. Pell, of the Nebraska University, in a large mound of unknown age near the site of a prehistoric village in Nebraska. The skull was that of a middle age man which showed abnormally highly developed eyebrow ridges, intermediate in degree between Neanderthal man and 'modern' man. On the evidence of these supra-orbital ridges it was at first thought that the skull might be included in the Neanderthal group. It has now been subjected to a close analysis by Dr. Hrdlička, whose decision is not only adverse to any close affinity with Neanderthal man, but definitely rules that it comes within the 'modern' group, on the evidence that in all its characters, excepting the eyebrow ridges, it belongs to the type of the modern Indian. In discussing the skull (*Amer. J. Phys. Anthrop.*, **20**, 2), Dr. Hrdlička goes on to point out that while the high development of these ridges may be regarded as evidence of "an ancestral connection with Neanderthal Man somewhere outside America" it does not show uninterrupted filiation, nor can it serve as an index of antiquity.

Recent Acquisitions at the British Museum, Bloomsbury

Among the recent additions of archæological interest, which are described in the *British Museum Quarterly*, **10**, 1, is a striking example of the artistic ability of the early Maya in the form of a cup with painted ornament, which has additional claim to attention in the fact that it comes from so far south as San Salvador. Especially important for students of early Buddhist art in India is a series of stucco figurines, twenty-five pieces in all, of which eighteen are heads, obtained by the French Archæological Delegation in Afghanistan in 1926–28, at Hadda, about five miles south of Jalalabad. In accordance with the policy, foreshadowed at the time of the acquisition of the Eumorfolpoulos collections, of devoting space in the *Quarterly* from time to time to descriptions of especially important examples of the art and culture of the Far East, two notes with illustrations deal respectively with a bronze of the Chou dynasty (1123–249 B.C.) and painted bricks of the succeeding Han dynasty. The bronze bowl or *tui* for holding cereals on ceremonial occasions,

such as the worship of ancestors, is one of the finest of the few which exist outside the Peiping Palace collections, and is otherwise remarkable in that it has four handles. It is highly ornamented with conventionalised designs including elephant heads and, possibly, stylised tigers. It has an inscription of sixty-nine characters, which is perfectly legible, though interpretations vary. The bowl would appear to commemorate a grant of land, for services rendered, to the Marquis Hsing by an emperor, conjecturally identified as Ch'êng (1115–1078 B.C.) The group of three painted bricks form a pediment which comes from a Han tomb. On them is a free and spirited symbolical design which is here interpreted as expressing the form taken by the Taoistic belief in life after death under that dynasty.

The Typhoon of September 21, 1934, in Japan

WHAT is described as the greatest typhoon on record struck the southern coast of Japan early on September 21. A week later, the Earthquake Research Institute sent several of its members to the district, and their reports on various features of the typhoon are included in a special volume of the Institute's *Bulletin* (Suppl. vol. 2, 302 pp. and 34 pls.). All the nine memoirs are written in Japanese, but, with two exceptions (mainly in tabular form), they are followed by summaries in English. The typhoon was generated at sea, in about lat. 11° N., long. 141° E., on September 13. It was then weak, and travelled slowly towards the north-west. A week later, near the Ryukyu Islands, its course changed to north-east. When it reached Sikoku, on the southern coast of Japan, its centre showed a pressure of 22·4 in., probably a record for land stations. The typhoon then passed over the adjoining districts, causing much damage to houses and trees, but it is worthy of notice that some earthquake-proof school buildings withstood a gale of 134 miles an hour. The main damage occurred in the coastal districts, and was due partly to the sea-waves, or kaze-tunami, raised by the typhoon and partly to a sudden rise of the sea that at Osaka ranged from 9·5 to 18·7 ft., and at Kobe from 5·8 to 6·5 ft. Among the causes of this abnormal rise, Mr. R. Takahasi includes a suction-like action on the sea-water due to the low pressure in the centre of the typhoon-path and the drift of the water to the coast by the force of the winds. Farther on, the typhoon passed over Lake Biwa, generating seiches with amplitudes of 10 in. and a rise of the same amount in the northern half of the lake, due again to the drift of the water. Even in the neighbourhood of Tokyo, the sea-level rose by about 4 ft.

British Association Seismological Committee

DURING the past year, the Committee has lost two of its members, Sir Horace Lamb and Prof. H. M. Macdonald. Two former members, Sir Alfred Ewing and Sir Arthur Schuster, also died since the last report was issued. The year has been marked by the publication of some important memoirs by members of the Committee. Two of them are on microseisms by Mr. A. W. Lee, who has shown that the average amplitudes of the east and vertical components of the microseisms recorded at Kew in 1932 were equal, and that microseisms usually approach England from the north-west, and are associated with storms in the Atlantic. A valuable memoir on the times of transmission of earthquake waves by Dr. H. Jeffreys and Mr. K. E. Bullen has been published by the International Seismological Association (*Trav. Scie.*, Sec. A, Fasc. 11; 1935), the inclusion of the summaries for individual earthquakes having been rendered possible by a grant from the Gray-Milne fund. A new catalogue of earthquakes, for the years 1925–30, has been prepared by Miss E. F. Bellamy from the International Seismological Summary. The form is the same as in the earlier number for 1918–24, edited by Prof. Turner, of which it is a welcome and very useful continuation. The International Seismological Summary for the first quarter of 1931 is in the press.

River Dee (Aberdeenshire) Flow Records

THE private organisation under the direction of Capt. W. N. McClean, known as River Flow Records, has continued its survey of the River Dee, undertaken in connexion with the British Association meeting at Aberdeen in September last year, and has recently issued two sheets of diagrams covering the period January–June inclusive of this year, together with an explanatory memorandum which states that the diagrams represent readings of water-levels and river flows from a catchment area of 528 square miles, and that they include meteorological records of rainfall, temperature and wind over the same district. As the result of the study of these observations of the Dee area, which have now been kept for a year and a half, it is found that in a comparison of rainfall and run-off, the former is underestimated. There is no actual measurement on the high mountains, and it may be said that rainfall measured in a rain-gauge is generally under-estimated; so that rainfall is admittedly only an approximation, whereas the measurement of flow by means of 'the most perfect apparatus existing in the country' is comparatively accurate. In the six months' period, the net aggregate of storage and run-off has reached just less than 19 in. out of a gross rainfall of 22½ in.

Electric Progress in Palestine

LORD READING, the chairman of the Palestine Electric Corporation, said at the annual general meeting on September 5 that electricity has played a leading part in the rapid economic development of Palestine. Last year the Corporation's revenue increased by 64 per cent, and 13,460 new consumers were connected. The generating plant now exceeds 40,000 kilowatts, and the existing transmission line from the first Jordan power house to Tel-Aviv will, at the present rate of growth, soon become inadequate to meet the consumers' load. Hence, a 12,000 kw. turbo-generator with the requisite boiler plant, transformers and switchgear has been ordered, and a second 66,000 kilovolt-transmission line will be

constructed. On the upper reaches of the River Jordan and Lake Tiberias, surveys are being carried out with the view of further hydroelectric development. Lord Reading stated that the demands in the Corporation's area are still far from the saturation point. As the policy of reducing tariffs wherever possible is being continued, the prospects are promising. As Palestine is practically a 'new' country from the economic point of view, it is not surprising that the company is already on a remunerative basis.

Sedimentation

BULLETIN 98 of the National Research Council of America (1935, pp. 246) embodies the report of the Committee on Sedimentation for 1932–34, and indicates the immense activity of investigators in this subject as well as of the members responsible for the report. The latter includes about a thousand references to current literature and in itself represents a commendable example of bibliographic and abstracting work. The topics discussed include European studies and varved sediments (Antevs); German contributions (Becker); studies at Stanford University (Blackwelder); glacial sediments (Leighton and Townley); British researches (Milner); mineralogy of sediments (Pettijohn); hydrologic and hydrographic investigations (Piper); chemical aspects (Steiger); recent sediments and petroleum source-beds (Trask); miscellaneous types (Twenhofel); marine bottom deposits (Vaughan); oxidation-reduction conditions in the Gulf of Catalina (ZoBell); and terminology of coarse sediments (Wentworth, with notes by Boswell). The last of these is a contribution of very general interest. The Sub-committee on Nomenclature and Classification of Sediments is studying the terminology of eleven groups, and in his introduction to the present report, Trowbridge holds out the prospect that following up the two reports already issued on volcanic and coarse sediments, others may be expected at the rate of two or more per year. The Committee is to be congratulated on the thoroughness of its work. It is obvious that without such a review geologists could not possibly keep in touch with the widely varied results of current progress in a branch of their science which is fundamental to its main object and to many of its applications.

Mining Legislation in South Australia

WE have received from the South Australian Department of Mines the *Mining Review*, No. 61, for the half-year ended December 31, 1934. After a short preface signed by Dr. L. Keith Ward, director of mines and also Government geologist, whose report appears afterwards, the review contains a summary of mining legislation, etc. A statistical portion which, together with a table at the end of the volume, shows that the total value of the minerals produced in South Australia since 1841 up to the end of 1934 equals 53¼ million pounds, taking gold at its old value. They also show a considerable increase both in quantity and value in 1934 compared to 1933, the quantity of iron ore produced in the former year being practically 1¼ million tons, showing an increase of half a million tons over 1933. Gold has naturally increased both in quantity and in value, and most other minerals show increases, though these in some cases are but slight, and actually show decreases in a few cases. Next comes a statement as to subsidies, from which it would appear that the amount advanced to various mines is nearly £71,000, of which a little more than £18,000 has been repaid. Next we have certain reports of treatment works and Government boring operations, followed by a short report by the Government geologist, and a series of reports by the chief inspector of mines, which give much detailed information about many of the mines of the Province.

Research on Shellac

IN 1925, the Indian Government founded the Lac Research Institute to ensure that the rapid development of rival products, and the high price levels reached in the post-War period, did not cause lac to meet the same fate that indigo had suffered previously. The results obtained during the first nine years work of the Institute and the present trend of the investigations have recently been published as an illustrated booklet in concise, interesting and non-technical form ("Lac and the Indian Lac Research Institute", by D. Norris, P. M. Glover and R. W. Aldis. Nankum: Lac Research Institute. Rs. 2.8). The lac insect yields both a colouring matter and a resin, and it was for the former product that it was originally cultivated. With the discovery of aniline dyes, however, the lac dye industry came to an end and the resin in unmanufactured form as lac, or the manufactured form as shellac, became the important feature of the industry. The uses to which shellac can be put are numerous, but the greatest proportion is adsorbed by the gramophone, electrical and varnish trades. The increasing use of synthetic resins such as bakelite inevitably threatened the industry, but as new methods have now been discovered whereby the natural product may be used in competition with the synthetic, the situation has improved. Research work is carried out on entomological, chemical and biochemical lines, many problems naturally occurring with regard to the insect and its host plant as well as the secretion of lac and its preparation for the market.

All-India Institute of Hygiene and Public Health

IN the annual report of the All-India Institute of Hygiene and Public Health, Calcutta, for 1934, the first to be issued, the events which led to the foundation of an All-India Institute of Hygiene are first recapitulated. The conception of providing courses of post-graduate training in public health originated with Sir Leonard Rogers, and as a result of his efforts the Calcutta School of Tropical Medicine was founded and opened in 1920. It was realised that there was also need for the training of an Indian personnel in public health, but circumstances prevented the realisation of this object until the Rockefeller Foundation offered to provide funds for a site, and for the

building and equipment of an institute, provided the Government of India undertook its maintenance. A site was acquired in 1930, and the building erected adjacent to the Tropical School, which was opened in 1932. The work of the Institute is carried on in six sections, and a representative staff has been appointed under the directorship of Lieut.-Col. A. D. Stewart, who is also the professor of hygiene. A description of the building is given, together with an account of the work of the sections, and of the research work that is in progress.

Food Poisoning

THE Ministry of Health has issued a memorandum on the steps to be taken by medical officers of health (outside London) in suspected cases of food poisoning (Memo. 188/Med.). The two classes of food poisoning are dealt with—contamination of food by poisonous chemicals and bacterial infections of food, which are far more frequent. Directions are given outlining the methods of investigating outbreaks, the collection of material for chemical or bacteriological examination, and method of packing and transmission to the Ministry, with hints on the chemical or bacteriological examination. In an appendix, a scheme is outlined for the routine inquiry into outbreaks of poisoning by meat foods, and in a second appendix valuable details are given for the isolation and identification of the bacteria (*Salmonella*) concerned in bacterial food poisoning.

International Congress on Soil Science

THE papers presented to the third International Congress on Soil Science, held recently at Oxford, embody work that is representative of most aspects of soil science; these are issued in two volumes (London: Thomas Murby and Co., 1935). The first volume contains those presented to the several commissions, and the second includes papers read at the plenary sessions, together with the address of the president, Sir John Russell. The papers are in English, French or German. The president, in his address, dealt with the contribution of soil science towards improving economic conditions, mentioning in particular the value of the surveying and mapping of soils as a preliminary to all schemes of agricultural development. As interesting examples of such contribution, those mentioned by Hardy, in his paper on "Some Aspects of Tropical Soils", may be quoted; these dealt more particularly with quantitative soil profile investigations. In the Caribbean region, for example, studies of this nature have rendered possible the exact definition of soil best adapted to the growth of several important orchard and field crops, and have made manifest certain soil factors that are definitely harmful to those crops. This aspect of soil work was dealt with by the commission on soil genesis, morphology and cartography and by that on the application of soil science to land amelioration.

No part of soil science stands to gain more from a Congress of this nature than that represented by those two commissions, since work in this field would lose much of its value without uniformity in methods of approach and expression of results. Studies on the composition and structure of the soil, divided for the purpose of the Congress into four commissions, namely, soil physics, soil chemistry, soil microbiology and soil fertility, reflect the progress that has been made in recent years in this aspect of soil work. Schofield made a contribution in which soil moisture relationships are regarded from a new point of view based on energy considerations, and introduced a scale to specify the degree of wetness or dryness of a soil; it was shown that by carefully distinguishing wetting from drying conditions, a more rational interpretation could be applied to data on plant wilting and field moisture capacity.

Cooke's Illustrations of British Fungi

A MAGNIFICENT series of eight volumes of "Illustrations of British Fungi" appeared towards the close of the last century. They were the work of Dr. M. C. Cooke, and served as a very pleasing and facile reference for naming the larger fungi. More recent advances in the scientific nomenclature of the Basidiomycetes, however, have shown that the names attached to the plates were not always correct. A great deal of confusion has resulted, and has somewhat diminished the usefulness of the work. Mr. A. A. Pearson has largely remedied this state of affairs, by publishing a modernised index to the "Illustrations" (*Trans. Brit. Mycol. Soc.*, **20**, Pt. 1, 33–95, Aug. 1935). This was originally based on notes prepared by Dr. Quélet, but Mr. Pearson also obtained the opinions of Prof. René Maire and Mr. Carleton Rea. These authorities concur upon a large number of species, but are by no means agreed upon others. The student of mycology will, however, be able to find the highest common factor between them where necessary, and will be able to use his Cooke's "Illustrations" again, with reasonable accuracy.

Fossil Elephants in Eldorado

A NOTABLE discovery of the remains of the extinct Columbian elephant, one of the largest of elephants, is recorded from Eldorado, Oklahoma, by Science Service, Washington, D.C. The University of Oklahoma and Kansas State College have united in excavating certain mounds in which casual digging had revealed fossil bones, and the first results include seven skulls and many bones, tusks and teeth of the species referred to. The elephant remains range from those of mature individuals to young ones, five to seven years old. In addition to these remains, bones of extinct species of camel, horse and bison have been excavated. It appears that the area of the discoveries was an ancient water-hole which had a bottom of very soft mud in which the animals had become bogged.

Guide to Statistics

THE "Guide to Current Official Statistics of the United Kingdom", for 1934 (H.M. Stationery Office. 1*s.*), has recently been published. This guide, now in its thirteenth year, has become almost indispensable

to all workers who have to deal with blue books and other official papers. It is so arranged that with a minimum of delay it is possible to find what statistics are available on any given subject. The degree of analysis of the figures, the dates and places to which they apply, and the price of the volumes containing them can be readily found. There is also given a list of the publications of various Government departments arranged under the departments.

National Radium Commission

THE new National Radium Commission has been elected and consists of the following members: the Earl of Donoughmore (Chairman), Sir Cuthbert Wallace (Vice-Chairman), Dr. T. Carnwath, Dr. T. Ferguson, Dr. Rupert Hallam, Dr. G. W. C. Kaye (appointed by the Department of Scientific and Industrial Research), Prof. J. C. G. Ledingham (appointed by the Medical Research Council), Mr. J. J. M. Shaw, Mr. G. F. Stebbing, Prof. Beckwith Whitehouse, Prof. James Young; *Joint Secretaries*, Dr. G. W. C. Kaye and Mr. G. F. Stebbing; *Office Secretary*, Miss K. Griffiths. The Commission will meet as heretofore at 5 Adelphi Terrace, Strand, W.C.2.

The Sky in October

ALL the naked-eye planets are now absent from the evening sky except Saturn, which is conspicuous and fairly well placed for evening observation: the stellar magnitude will decline from $+ 0{\cdot}8^m$ to $+ 1{\cdot}0^m$ during the month, but the planet is rather far south, as also was Jupiter this summer, Saturn's declination being $-11° 50'$ on October 15. Venus is now an early morning object, and will attain its greatest brilliance on October 15. Mars and Jupiter are both near the sun. Uranus will be in opposition on October 27, and there will be a conjunction of Neptune with Venus on October 25, Venus being 2° 6′ S. The minor planet Vesta is now in the evening sky, not far from Saturn. Intensive observations on the minor planets have been started at Greenwich, in pursuit of a plan for making greater use of these small objects for determining the position of the equinox. They just show a disc in the 8-in. transit telescope, but resemble a star far more closely than does Venus (and *a fortiori* the sun), so that the minor planets are very suitable objects to observe in order to tie up the right ascensions and declinations of the solar system with the fundamental right ascensions and declinations of the stars. The principle involved is that the observation of a planet from the earth is equal and opposite to an observation of the earth from the planet, so that besides observing the planet's orbit we observe our own, and find the point where our orbit cuts the equator, that is, the equinox.

Announcements

THE opening lecture of a series on "Scientific Progress" organised by the Sir Halley Stewart Trust will be given by Sir James Jeans in the Memorial Hall, Farringdon Street, London, on Tuesday, October 22. The subject will be the new world picture as seen by the modern physicist. Other contributors to the series are Sir William Bragg, Prof. E. V. Appleton, Prof. E. Mellanby, Prof. J. B. S. Haldane, and Prof. Julian Huxley. Free reserved tickets are obtainable from the Trust, 32 Gordon Square, W.C.1.

THE Robert Koch medal has recently been awarded by the City of Berlin to Dr. Ferdinand Sauerbruch, professor of surgery in Berlin, the Emil Fischer medal to Dr. Adolf Butenandt, professor of organic chemistry and technology in Danzig, and the Liebig medal to Dr. Walther Roth, professor of physical chemistry at Brunswick.

A LECTURE on the work of the expedition of the Egypt Exploration Society (2 Hinde Street, W.1) to Tell el-Amarna 1934–5 will be given by the field director, Mr. J. D. S. Pendlebury, on Monday, October 7, at 8.30 p.m. in the rooms of the Royal Society, Burlington House, Piccadilly, London, W.1.

THE sixtieth series of free lectures at the Horniman Museum, Forest Hill, S.E.3, will begin on October 12 at 3.30, when Mr. E. C. Stuart Baker will lecture on "Wild Men and Wild Beasts in India". Further information can be obtained from the Curator of the Museum.

IT has come to the notice of the National Institute of Agricultural Botany that a Danish 're-selected' stock of Resistance Oats is being offered on the English market. The Institute desires to state that no seed of this variety was distributed prior to the autumn of 1934.

THE Electrodepositors' Technical Society, which has been responsible for the organisation of the Electrodeposition Exhibition in the Science Museum at South Kensington, will hold a Soirée in the Museum on October 18. The Exhibition will be open from 6.15 until 10.30 p.m., during which time a lecture will be given by Mr. S. Field on progress in electrodeposition and a film will be shown dealing with commercial applications of electrodeposits. Admission to the Museum will be by ticket. The Society welcomes applications from members of kindred societies and institutions and from others interested in the theory or practice or applications of electro-deposition. Applications should be made immediately to the assistant hon. secretary, Capt. A. I. Wynne-Williams, 12A, Raleigh House, Larkhall Estate, London, S.W.8.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

An assistant in the London Museum, St. James's, S.W.1—The Keeper (Oct. 28).

A secretary for the Society for Cultural Relations with the U.S.S.R., 21 Bloomsbury Square, London, W.C.1—The Chairman.

A woman lecturer in geography and mathematics in St. Hild's College, Durham—The Principal.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 554.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Physical Units and their Dimensions

HAVING an interest in astrophysics, and chemistry, and telegraphy, for each of which some knowledge of electrical quantities and relations is required, more than I can carry in my head, a problem arises where to find it. It has been solved for my case by use of a single page appendix to a treatise on astronomy, which I keep handy with the page turned down, and which provides all that I need. I would not dream of remembering the complexities of nomenclature of an electrotechnical handbook. I observe that all this is now in the melting pot again, with its 'gilbert, gauss, oersted and maxwell' and so on, under new international auspices of some kind, to judge by letters in NATURE which I do not comprehend even by guesswork. Do the technicians of the great industrial corporations really desire to cut themselves off from the general sciences, or do they merely ignore this activity as a play of professors ?

I am old enough to remember the beginnings of standard technical units, first in Kelvin's laboratory owing to the needs of submarine telegraphy, extended later to marvellously precise measurements mainly in the Cavendish Laboratory under Rayleigh's guidance, with results in values and nomenclature adopted into a universal practice mainly through Kelvin's international diplomatic gift. Once the now familiar c.g.s. unitary frame was adopted, the relevant electric unitary quantities followed, from their mutual relations in terms of one of them, thus forming a linear system, their dimensions as deduced from illustrative examples relative to the frame presuming that their relations are for all such examples of mutually consistent mechanical type.

It appears that the electrotechnicians are now invited to inhabit a world of their own in which c.g.s. are replaced by M.K.S., one moreover in which even the classical electrodynamic equations may be replaced by new ones peculiar to them. The standard units on the original c.g.s. frame were indeed in like manner too small for practical electric purposes, and were changed by the original founders to a secondary system affected by powers of 10, for example, a secondary unit concisely specified as 10^8 c.g.s. being named out of international compliment a volt, and so on. This correlation by factors that are powers of 10 appeared to be simple and universally acceptable. But these secondary units must also be bound together by a basic system of their own, to replace cm., gr., sec. I find on consulting § 620 of the relevant chapter (not too lucid) of Maxwell's "Treatise", a book now almost as obsolete as the "Principia", that this necessary basic system is 10^9 cm., 10^{-11} gm., sec. Thus the secondary unit of mechanical force would be 10^{-2} dyne, and so on: on the M.K.S., namely, 10^2 cm., 10^3 gm., sec. frame now apparently proposed, it would be 10^5 dyne. These extensions into mechanics have, however, hitherto been scarcely thought of: while the concise device of powers of 10 as ratios of the units of the same entity that arise has proved precise and adequate without divorce of electrotechnic theory from the scheme of general science. Why cannot it be let alone ? But, by the way, on the other side of this account, may not the use by theorists, now introduced into Britain, of the hybrid electric unitary system favoured by Helmholtz, be a cause of dimensional inconsistencies as possibly felt by practicians ?

A deeper analysis in this regard, indicating a wider significance, is suggested. To secure unambiguous dimensions, the units must be a linear scheme with freedom of transformation backwards and forwards. This can be so, because there is presumed to be a unique ultimate theory which has to be on a mechanical basis as resting on length, mass, time, a presumption which might be called the Kelvin postulate. But regions of this final connected map of phenomena are concealed, and the partial effective theories, for example, the familiar electrostatic and the electromagnetic developments, are built up by working round these blank regions in different ways, establishing contacts where feasible while *ex hypothesi* they cannot show mutual contradictions. Thus, the test that every term in a summation formula must have the same dimensions is an indirect probe that the formula conforms to this unique ultimate foundation scheme. The assignment of dimensions to K or μ, after Rucker, promotes this unification of all systems of units virtually by adding a fourth variable to the c.g.s. three. The deeper significance for dimensions thus indicated has its origin historically with Gauss and Weber, rather than with Newton or Fourier; for they explored and compared the two widely removed paths of experimental entry into what proved to be the same range of phenomena of electrics, and identified them as far as might be; as is illustrated by Weber's recognition that the two resulting modes of measure of charge must be connected in terms of a velocity, while his experiments indicated, almost before its time, in advance of theory, that the velocity of light is here involved.

Magnetic Storms and Upper-Atmospheric Ionisation

Now that measurements of upper-atmospheric ionisation can be made, using methods of radio exploration, it is of interest to see whether abnormal values of ionisation density are associated with periods of magnetic activity. We have conducted such an inquiry using the measurements of ionisation density in Region F_2 of the ionosphere made at the Radio Research Station, Slough, together with the daily magnetic character figures from the Abinger Observatory supplied to us by the Astronomer Royal.

Since magnetic activity is, in this latitude, most pronounced just before midnight, we have taken the midnight values of the critical penetration frequency of Region F_2, which is a measure of the maximum electron density, as the daily index of ionisation, and compared it with the magnetic character figure for the preceding twenty-four hours. In order to allow for the seasonal variation of ionisation, the daily departure of the critical penetration frequency from the appropriate value on a smooth curve drawn through the monthly means has been used as expressing whether a particular daily value was abnormally high or low.

The results of this examination show that when there is a small amount of magnetic activity the ionisation is above normal, but that when the activity is more severe the critical frequency is much depressed, indicating a reduced value of the maximum electron content. The correlation factor for the two quantities, (1) departure of midnight critical frequency from normal, and (2) magnetic character figure, has been found to be $-0{\cdot}247$ for the year 1934, thus showing the slight preponderating influence of the negative correlation with large storms.

Now an increase of ionisation density would receive a ready explanation in terms of current theories of the production of magnetic storms by the injection in the upper atmosphere of ionising particles from the sun, but a decrease of ionisation density seems more difficult to explain. It has, however, been recently shown[1] that the abnormally low daytime ionisation densities observed in summer for Region F_2 are to be attributed to the influence of atmospheric heating by solar radiation. It seems possible to explain the low value of night-time maximum ionisation density associated with marked magnetic activity in a similar manner. If the agency responsible for magnetic disturbances heats the upper atmosphere so that it expands, the maximum electron density will be correspondingly reduced.

A study has also been made of the connexion between magnetic activity and noon values of maximum ionisation in Regions F_1 and F_2, but here the results obtained are not quite so simple. It is true that intense storms are often accompanied by marked reductions in the critical frequencies of both regions, and especially is this found to be the case at the equinoxes, but we have noted a number of cases where the critical frequencies are actually markedly increased when a large storm is in progress. More often than not, the departures of the critical frequencies for the two regions from the appropriate mean curves are in the same sense, though they are much greater for Region F_2 than for Region F_1. An inverse correlation between earth currents and Region F_1 ionisation has already been noted by Schafer and Goodall[2], but they were unable to find any connexion in the case of Region F_2 ionisation.

This work has been carried out as part of the programme of the Radio Research Board of the Department of Scientific and Industrial Research.

E. V. APPLETON.

Hydrogen in the Upper Atmosphere

ONE of the most striking characteristics of both auroral and night-sky spectra is the absence of hydrogen lines. So far as I am aware, not even a trace of the atomic or molecular spectra of hydrogen has ever been observed in either of the above spectra. The question is immediately raised, does this absence prove that there is no hydrogen in the upper atmosphere at the heights at which night-sky and auroral spectra have been photographed? It is the purpose of this note to discuss briefly the answer to this question.

In order to do this, it is necessary to recall some of the recent experiments carried out by me on the laboratory production of auroral and night-sky spectra. In order to produce either of these spectra, it is necessary first to prepare an uncondensed electrical discharge in nitrogen which is accompanied by a strong afterglow. It must be pointed out here that the best known nitrogen afterglow is the one which accompanies a condensed discharge in nitrogen, and that it was not until 1931 that the afterglow accompanying uncondensed discharges was discovered. It is much more difficult to prepare a tube which will show an afterglow when an uncondensed discharge is passed through it than one which will show the afterglow with a condensed discharge. In fact, the former afterglow was discovered in a tube which had been run for about two weeks during which all the impurities such as oxygen, carbon compounds and hydrogen were cleaned up. After many trials it was found that the preparation time could be greatly shortened if hydrogen were not present in the initial gas. Thus, in preparing tubes at the present time, whenever the tube fails to show an afterglow immediately, it is pumped down, say, from 10 mm. to about 10^{-3} mm. and in every case H_α and H_β are present in the light emitted by the tube. Repeated experiences show that a very small amount of hydrogen completely changes the spectrum and behaviour of nitrogen tubes. When it is present, no afterglow accompanies the uncondensed discharge, and when it is absent the discharge is accompanied by a strong afterglow the spectrum of which is that part of the auroral spectrum that is emitted by nitrogen.

The hydrogen may inhibit the afterglow by being adsorbed on the walls of the tube, thus preventing the adsorption of nitrogen atoms and their subsequent recombination to form the metastable molecules which seem to be necessary for the existence of nitrogen afterglows. The effect of the hydrogen may, however, be a space, rather than a surface, effect. If this should be true, then one must conclude that there is so little hydrogen in the upper atmosphere that it does not prevent the production of the auroral spectrum. In fact there should be a steady change of the auroral spectrum with the amount of hydrogen present in the region where it originates.

Before it will be possible to use the effect of hydrogen on the nitrogen afterglow, to study the hydrogen in the upper atmosphere it will be necessary to distinguish between space and surface effects. Experiments are now in progress to achieve this. Should it turn out to be a space effect it will be necessary to study the changes in auroral spectra with height.

In closing, it should be pointed out that several authors have identified certain night-sky spectra in

the red as water-vapour bands. While this identification is not certain, it at least suggests that the hydrogen in the upper atmosphere is present as part of the water molecule. While this may be reasonable for the light of the night-sky, one would expect water-vapour to be dissociated during auroral displays. Furthermore, no water-vapour bands have been observed in auroral spectra.

Although the present evidence is not conclusive, it was thought worth while to direct attention to this remarkable effect of hydrogen on the nitrogen afterglow and to its possible relationship to the question which was put at the beginning of this note.

Statistical Tests

PROF. FISHER[1] is an apt controversialist, but he knows as well as I do that what I understand by *graduation* is not confined to *curves*; that I should term graduation the fitting of a binomial to a series of observations, or the determining whether a system of correlation coefficients could be reasonably supposed to have arisen from samples of material drawn from a population with a given correlation coefficient. The difference between Prof. Fisher and myself lies in the use (and abuse) of the acceptance and rejection of 'hypotheses'. There is only one case in which an hypothesis can be definitely rejected, namely, when its probability is zero. He cites a case which I criticised in the paper he refers to, in which two recessives (say) had produced a dominant, and theory was absolutely contradicted. It did not require an *application* of the (P, χ^2) test to assert that either theory or observations must be rejected! I merely showed that the (P, χ^2) test did not fail in this case. But let us look into what actually happens, and I cannot do better than illustrate it on some statistics provided by Sir James Jeans in NATURE of September 14, 1935 (p. 432). He is comparing the eccentricities of visual binaries, 116 in number, against a theory of equipartition (not a *curve*, but frequencies are considered). His data expressed by a frequency series run as follows :—

Eccentricity.	Observed.	Theory for 116 stars, $e<1$	Theory for 83 stars, $e \leqslant 0{\cdot}06$.
0·00–0·01	0	4·5	9
0·01–0·02	11		
0·02–0·03	9	6	12
0·03–0·04	14	8	16
0·04–0·05	24	10·5	21
0·05–0·06	25	13	25
0·06–0·07	6	15	—
0·07–0·08	13	17	—
0·08–0·09	7	20	—
0·09–1·00	7	22	—

If the P, χ^2 test be applied to the total 116 binaries, we have $P < 0{\cdot}000{,}0005$. On the other hand, if it be applied to the 83 stars of lowest eccentricity, $P = 0{\cdot}79$. In neither case can you say the hypothesis is true or false. You reject it in the former case because it is a poor graduation, you say in the latter case that it is a reasonably good graduation because 79 per cent of random samples would, were the 'hypothesis' true, give a worse result than the observations do. But in accepting it as a working graduation, you do not assert its truth any more than you assert the falsity of the hypothesis applied to the whole 116 stars; you merely say the latter is a bad graduation, and try for a better. Had Sir James Jeans taken all stars with eccentricity $\leqslant 0{\cdot}07$, instead of $\leqslant 0{\cdot}06$, he would have found $P = 0{\cdot}105$, and if he had proceeded to $e \leqslant 0{\cdot}08$, the result would have been $P = 0{\cdot}00001$, that is, he might have got a worse sample in 100,000 trials. Actually he gives his reasons for cutting off the higher eccentricities. With them I am not concerned, although the exact cutting off at $e = 0{\cdot}06$ is not discussed; the difficulty of detecting high eccentricity binaries and of then determining their orbits may account for the irregularity of the last four frequency entries, as he holds, or there may be other reasons why the falling-off occurs at $e = 0{\cdot}06$. *Hypotheses non fingo!*

Now Prof. Fisher refers to rejecting hypotheses as a function of the P, χ^2 method, and of accepting them as a logical fallacy. I have in my letter of August 24 stated that the tests are there to ascertain whether a reasonable *graduation* has been reached; not to assert whether one or other hypothesis is true or false. We should accept Sir James Jeans's equipartition as a reasonable graduation for the observed binaries $e \leqslant 0{\cdot}06$ ($P = 0{\cdot}79$) and reject it as a graduation for the observed binaries $e \leqslant 0{\cdot}08$ ($P = 0{\cdot}000{,}01$). It is not for statisticians to say whether an hypothesis is false except when $P = 0$. All that they can legitimately say is that it gives a poor *graduation*. In particular, it is very unwise in *my* opinion to form tables which provide only the values of $P = 0{\cdot}01$ and $P = 0{\cdot}05$, and consider 'hypotheses' which give a value of $P < 0{\cdot}01$ as 'false', and those with a value between 0·01 and 0·05 as 'doubtful', and for the rest of the scale of P have no descriptive category, for you must not say that such values prove hypotheses to be true. Hence I repeat my assertion, in the face of all the authority of Prof. Fisher and his followers, that all the P, χ^2 test ascertains is goodness of graduation, and I hold that 'goodness' of graduation is relative to the nature of the material investigated, our experience of similar material and the purpose to which we intend to put our graduation. The value of P at which we consider goodness or badness of graduation starts cannot be fixed without regard to the special problem under consideration.

There seems somewhere a logical fallacy in the position of both Prof. Fisher and Mr. Buchanan Wollaston. They both apparently assert that the P, χ^2 test enables one to say an hypothesis is false, yet never to say that an hypothesis is true, but if an hypothesis be *false*, its reverse must be true. If you assert that the hypothesis that a sample is drawn from a normal curve is false, the reverse hypothesis that it is *not* drawn from a normal curve must be true. As a matter of fact, the P, χ^2 test has only measured its 'goodness of fit' by a probability coefficient, and it is as idle to say as a result of it, that the hypothesis is 'false', as that the reverse of it is 'true'. The only exception to this rule is when the observations show the existence of individuals in a frequency class which the hypothesis asserts cannot exist.

The 'laws of Nature' are only constructs of our minds; none of them can be asserted to be true or to be false, they are good in so far as they give good fits to our observations of Nature, and are liable at any time to be replaced by a better 'fit', that is, by a construct giving a better graduation.

Stereoscopic Photography

IN "A Note on Stereoscopic Photography"[1] Dr. John R. Baker refers to different methods of making stereoscopic photographs of near objects. There are two possibilities: the axes of the cameras can be parallel to each other, or they can be convergent to the object. Dr. Baker concludes: "The convergent camera gives the proper representation of the object". I think this conclusion is not right. Let us consider a moment a photograph made by a camera in an arbitrary position. It always represents reality if we look at it in the right manner. It is necessary to put the eye in the place occupied by the lens in making the photograph, and the different points of the image will be seen under the same angles as the corresponding points of the object. In Fig. 1 of Dr. Baker's article both photographs have to be seen from D and so A' and A'', B' and B'', and C' and C'' are seen in the same direction.

In choosing the right lenses for the stereoscope, it is possible to look at both photographs in the right manner. So each eye gets the same impression it should get in reality, and there is only left the possibility that both eyes, in looking to some detail, should have a position to each other different from that which they should have in reality. It is here there is a real difference between both methods. With convergent cameras we get the images of the object in the centre of the plate and in looking at them in the stereoscope the axes of the eyes will be parallel. With parallel cameras the images come more to the border, and in looking at them the axes of the eyes will be convergent. Here the effect of the parallel cameras is more according to reality, but the eyes are very insensitive to the difference. So the impression is the same in both circumstances.

It may be mentioned that one real advantage of the method of convergent cameras is a relatively big field of view, as only the common field of view of both cameras contributes to the stereoscopic impression.

J. VAN ZUYLEN.

Utrecht.

[1] NATURE, 136, 193; August 3, 1935.

IN looking at a near object, the eyes are turned inwards. Therefore to procure a really natural stereoscopic view of two photographs of a near object, the eyes should be turned inwards at the same angle. To achieve this, the two photographs should be mounted in such a way that the corresponding points in them are nearer than the interpupillary distance. With this arrangement, it is true that proper stereoscopic views may be obtained with photographs of near objects taken with parallel cameras; but if the corresponding points in the two photographs are separated by approximately the interpupillary distance (as in normal stereoscopic photography), a wrong impression is conveyed to the eyes.

Convergent vision with the stereoscope presents two difficulties. First, most people (as I have found by painful experience at conversaziones) are unable to fuse the images with a convergent stereoscope: when a person holds a stereoscope to his eyes, he reflexly directs his eyes for parallel vision. Secondly, the placing of the corresponding points in the two photographs nearer together than the interpupillary distance narrows the possible field of view.

For these reasons I nowadays keep to the standard stereoscope and use parallel vision, insisting only that to each eye there shall be presented exactly the view that would be obtained if one were looking at the object with one's eyes in the positions of the lenses of the cameras when the photographs were taken. This can only be achieved by using convergent cameras (or by using the equivalent, the tilting stage method, in stereo-photomicrography).

If the convergent stereoscope did not present the two disadvantages mentioned above, the ideal method for the stereoscopic photography of near objects would be the following. The photographs would be taken by convergent cameras (or by the use of the tilting stage). A convergent stereoscope would be used for viewing, and the two photographs would be arranged in the stereoscope in two different planes at right angles to the two lines of vision.

I wish to acknowledge the benefit of discussions on this subject with Prof. F. A. Lindemann and Mr. S. J. Baker.

Raman Spectrum of Heavy Water

THE Raman spectrum of heavy water was first studied by Prof. R. W. Wood[1], who obtained a strong band at 2517 cm.$^{-1}$. For the vapour of heavy water, Rank, Larsen and Bordner[2] found a line at 2666 cm.$^{-1}$, while Wood has reported a line at 2601 cm.$^{-1}$. These results are evidently incomplete. In view of the great interest attached to this substance, it appeared worth while to re-examine the matter, using 50 gm. of 99·2 gm./100 gm. D_2O (d_4^{20} 1·1049) supplied by the Norsk Hydro-Elektrisk Kvaelstofaktieselskab. The Raman spectrum of the substance was photographed with a Hilger two-prism spectrograph with about 72 hours exposure, and is reproduced as Fig. 1.

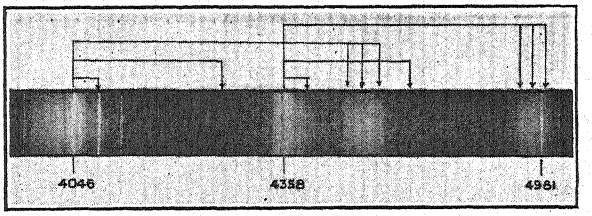

FIG. 1. Raman spectrum of heavy water.

The spectrum shows a number of interesting features which have not been noticed by the previous workers.

1. The principal band is seen to consist of three imperfectly resolved components of frequency shifts 2646 cm.$^{-1}$, 2500 cm.$^{-1}$ and 2366 cm.$^{-1}$. These correspond to the components 3630 cm.$^{-1}$, 3435 cm.$^{-1}$ and 3200 cm.$^{-1}$ reported for ordinary water, and indicate that heavy water is polymerised in a very similar way to ordinary water.

2. A new band with a frequency shift of 1231 cm.$^{-1}$ is very clearly seen with both the 4358 A. and 4046 A. excitations. Careful examination of the plate reveals faint components to this on either side, the central component of the triplet being by far the brightest. The position of this band compares

very favourably with the frequency 1250 cm.$^{-1}$ calculated from the theory of the molecular vibrations of three-particle systems put forward recently by Van Vleck and Cross[3]. It is interesting to note that a similar, but very feeble, band of frequency shift about 1650 cm.$^{-1}$ has been reported in the case of ordinary water[4].

3. A third band with a much lower frequency shift of 178 cm.$^{-1}$ is also noticed with both the 4358 A. and 4046 A. excitations. This frequency is far too low to be attributed to the internal vibrations of the D_2O molecule, and hence is presumably due to some sort of rotation or vibration of the molecule as a whole. The Raman spectrum of ordinary water also shows a band at approximately the same position. This band is evidently to be ascribed to the frequency of hindered rotation or oscillation of the liquid molecule, of which independent evidence is forthcoming from studies of dielectric constant[5], infra-red absorption[6], viscosity, etc.

A detailed paper on the subject will appear in the *Proceedings of the Indian Academy of Sciences*.

Diffusion of Heavy Water into Ordinary Water

W. J. C. ORR and D. W. Thomson[1] have found the velocity of diffusion of HDO into H_2O to be abnormally large, the diffusion constant D being 9×10^{-4} cm.^{2} sec.$^{-1}$ at 15° C., whereas for all simple substances in water, diffusion constants are of the order of magnitude 10^{-5} cm.^{2} sec.$^{-1}$. Since this result, if it were true, would be of considerable significance for the theory of the structure of water, experiments were made to verify it.

The velocity of diffusion was measured with a micropyknometer of E. S. Gilfillan and M. Polanyi[2]; the orifice was made larger than usual (namely, about 0·1 mm.) to make noticeable the diffusion from the body of the pyknometer into the surrounding water.

The method of carrying out the experiments was as follows:

At the beginning the difference $(\triangle P)_1$ in equilibrium hydrostatic pressure for the solution and ordinary water was measured. Diffusion from the pyknometer was allowed to occur, in a separate vessel at constant temperature and for a given length of time t, and the measurement of the difference in the equilibrium hydrostatic pressure was repeated, giving $(\triangle P)_2$.

From Fick's law, the following equation can be easily obtained:

$$\lg \frac{(\triangle P)_1}{(\triangle P)_2} / D\,t = K,$$

where K is a constant.

Constant K was obtained from observations of the diffusion of potassium chloride solution, employing data of the International Critical Tables for the diffusion constant. All experiments were duplicated, results agreeing within 5 per cent.

The following values of D were obtained for the diffusion of heavy water from ~ 3 mol. per cent solution into ordinary water.

$$D = 1{\cdot}1 \times 10^{-5} \text{ cm.}^2 \text{ sec.}^{-1} \text{ at } 0{\cdot}0^\circ \text{ C.}$$
$$D = 2{\cdot}5 \times 10^{-5} \text{ cm.}^2 \text{ sec.}^{-1} \text{ at } 28{\cdot}0^\circ \text{ C.}$$

Hence the constants are of the usual order of magnitude, contrary to the result of Orr and Thomson.

My thanks are due to Prof. M. Polanyi for the use of the micropyknometer apparatus and for much valuable discussion.

Identity of Natural Vitamin D from Different Species of Animals

BILLS, Massengale and Imboden[1] have found that one rat unit of blue-fin tunny liver oil in chicks has only 15 per cent of the antirachitic effect of one rat unit of cod liver oil, whence they conclude that the two forms of vitamin D are different. However, Dols[2] demonstrated that the antirachitic effect of these two forms of vitamin D in chicks is the same, the necessary dose being about 80 international D units a day for each chicken. Before the results of Dols were known to us, we had running a great number of tests to investigate whether there is any difference between the vitamin D of different species of animals. (The fact that there is another form of natural vitamin D found in green plants and accompanying the free fatty acids[3] is not discussed here.)

From the different fats under investigation the unsaponifiable fraction was first isolated, the vitamin A eliminated and the vitamin D to some degree concentrated by a method reported by us[4]. We have examined the liver fat as well as the body fat of the following species: coalfish (sei, *Gadus virens*), cod (torsk, *Gadus morrhua*), cusk (brosme, *Brosmius brosme*), dogfish (hå, *Squalus acanthias*), dorn (piggrokke, *Raja clavata*), Greenland shark (håkjerring, *Somniosus microcephalus*), haddock (kolje, *Gadus æglefinus*), halibut (kveite, *Hippoglossus hippoglossus*), herring (sild, *Clupea harengus*), mackerel (makrel, *Scomber scombrus*), pollack (lyr, *Gadus pollachius*), redfish (uer, *Sebastes marinus*), salmon (laks, *Salmo salar*), shark (håbrand, *Lamna cornubica*), sprat (brisling, *Clupea sprattus*), tunny (makrelstörje, *Thunnus thynnus*), wrasse or 'Old Wife' (berggylte, *Labrus berggylta*), blue whale (blåhval, *Balæna musculus*); we also had specimens of vitamin D from the liver and body fat of a cow and of a human female. We found no difference between the antirachitic effect in chicks of all these fats, the daily dose required being in all cases 70–80 international D (rat) units per chicken.

We were thus able to confirm Dols's results but not the results of Bills *et al.* with tunny liver fat None of the preparations investigated by us showed a maximum of absorption in the ultra-violet spectrum at 260–270 mμ nor any rotation of the plane of polarisation in alcoholic solution, and the degree of

esterification with phthalic anhydride and pyridine after 10 days was 100 per cent. Maleic anhydride had no effect upon the present vitamin D[4]. There is thus no evidence that the vitamin D in all the fats investigated is not the same. A detailed report will appear in the near future.

Effect of Low Temperature upon Trypanosomes (*Trypanosoma equiperdum*) in Mammals

THE study of dormancy and under-cooling of animals has shown that the process of cooling sharply slows down all physiological functions. Yet the decrease in the rate of different functions is not the same[1,2]. In connexion with these observations a new question has arisen: In what way will the fall of temperature of the body of an animal influence micro-organisms infecting it?

Experiments were made with two species of bats, namely, *Nyctalus noctula*, Schr., and *Pipistrellus nathusii*, Keys. et Blas, which were infected with *Trypanosoma equiperdum*. For inoculation, blood was taken from the tails of white mice when the number of trypanosomes in the blood attained 9–10 in the field of vision. Into the skin of the abdomen of bats 0·01 c.c. of blood was introduced. A group of these animals was kept in an active state at a temperature of + 20° to 25° to study the normal course of infection. The second group of animals was placed immediately after the inoculation into cold boxes with a temperature of + 10° and + 3°. Every day from the vein of the membrane of the 'wing', blood was taken and the number of trypanosomes was counted in the dark field. The temperature of the bodies of bats was determined by means of a thermopile as described previously[2].

Trypanosomes multiplied very quickly in the blood of bats in the active state. During the period of 4–5 days the number of parasites in the blood reached 10–20 in a field of vision, on the 6–7 day the trypanosomes were abundant, and on the 9–13 day the animals died.

In experiments with animals placed immediately after infection into ice-boxes with a temperature of + 10° and + 3°–4° it could be seen that the infection in the organism of bats does not develop during a period of 8–15 days. Having raised the temperature after the expiration of this period and having kept the bats in this condition for about 3–5 days, we were still unable to detect any traces of infection. Subsequent infection of them with a new virus was quite successful, which showed the absence of immunity. In other words, the absence of blood parasites was retained from the first infection.

We also conducted experiments by cooling the animals after infection had already developed. For this purpose, a group of active (control) animals, at the moment when the number of trypanosomes in their blood reached a high level, that is, 1–10 trypanosomes per field of vision, were transferred to ice-boxes. After a cooling period of 3–8 days (at temperatures of + 3° and + 10°) the parasites completely disappeared from the blood of the bats. 2–4 days after the disappearance of trypanosomes from the blood, the animals were warmed, and placed in the same conditions as those under control (with a body temperature of 33°–37°).

The blood of the bats during 2–5 days after their being warmed was also without any parasites. Experiments with repeated infection have shown the absence of immunity in the animals, in other words, the absence in their organisms of trypanosomes from the first inoculation.

Parexocœtus, a Red Sea Flying Fish in the Mediterranean

FLYING fish from the eastern part of the Mediterranean are very little known, and most identifications have not been controlled by comparison with material from the Atlantic.

Dr. E. Liebman, of Jerusalem, has recently sent me two specimens from the Palestine coast, both of which are adults (standard lengths 95–103 mm.) of the primitive genus *Parexocœtus*, Bleeker. *Parexocœtus* has not been recorded from the Mediterranean before. They belong to the species *P. mento*, C. and V., as defined in my recent revision of the Atlantic Exocœtids[1]; but whether they are derived from the Atlantic subspecies *atlanticus*, Bruun, or are of Red Sea origin may be questioned. Klunzinger's species *gryllus* from the Red Sea is certainly a *Parexocœtus*, and most likely a subspecies of *P. mento*. The numerical characters of the two specimens received (*D.* 9–10, *A.* 11, *P.* 13–14, vert. 36–37, gill-rakers 28–29) indicate closer relationship to *P. m. gryllus* than to *P. m. atlanticus*, which is only known from the Cape Verde region.

Therefore it seems very possible that *P. mento*, one of the neritic flying fish, has passed through the Suez Canal and found a new breeding place in the innermost, warmest part of the Mediterranean.

It would be of great interest to study closely the racial characters of the Mediterranean and Red Sea populations of this flying fish and the eight or nine other species of fish, which Liebman[2] has recently recorded as Red Sea immigrants into the Mediterranean. Naturally, equal interest would be connected with immigrants in opposite direction. If no investigator is available to take up this question at present, it is suggested that museums and biological stations of that region should take immediate steps to secure abundant material for a future study. The life-conditions in the two seas are so different that environmental influence, sooner or later, will almost certainly be traced in the immigrated stocks. In any event, this large-scale experiment on geographical differentiation deserves to be followed very closely.

Organic Soils and Epinastic Response

CONSIDERABLE interest is being shown at the present time in plant auximones and the chemical regulation of plant growth. Traces of many substances have been found to influence growth profoundly. Such substances range from complex or as yet chemically unidentified bodies produced in the growing regions of plants to quite simple chemical substances produced by plant tissues or in the laboratory.

Among the latter is the gas ethylene which, when present in the air in amounts of the order of one part per million, produces characteristic effects on tomato, potato and other plants specially sensitive to it[1]. In the case of tomato, the most obvious reactions to traces of ethylene are: (1) stimulation of growth on the upper sides of petioles inducing characteristic epinastic curvatures, (2) stimulation of the formation of root primordia associated with inhibition of root growth—copious root growth occurring as soon as the treated plant is removed from the ethylene atmosphere. These reactions have been used to detect the presence of traces of ethylene and certain other gases, and it appears that the evolution of ethylene is a frequent accompaniment of plant metabolism, particularly during the ripening of many fruits[1].

In view of these facts it may be of interest to place on record some results of recent experiments of my own with certain infertile organic soils. Without entering into details, the following facts appear to be established. (1) A gas may be extracted from such soils (by aeration, centrifuging or heating) which produces on tomato plants epinastic curvatures of the petioles similar to those brought about by traces of ethylene. (2) Extracts from such soils when added to water culture solutions produce similar epinastic curvatures on cuttings and influence the rooting of cuttings and the manner of root growth of cuttings and seedlings. There are indications that the intensity of these effects is seasonal.

Comparison with soils of other types in relation to these effects is being carried out, and the results of the work will be published in due course.

In view of the known effects of gases such as ethylene in stimulating the formation of root initials and controlling the growth of roots, it seems not improbable that failure or success in the establishment of a root system on the part of seedlings in some soils may be influenced by the presence in the soil atmosphere of varying amounts of ethylene (or other gases producing similar reactions), the origin of which doubtless may be sought in the decomposition changes taking place in the organic constituents of the soil following upon biological activities.

Points from Foregoing Letters

SIR JOSEPH LARMOR expresses his disapproval of the introduction of the new meter-kilogram-second system of units. He considers that the c.g.s. units, expressed in powers of ten, are adequate; he inquires, on the other hand, whether the Helmholtz system of electrical units may lead theorists astray.

Measurements of the ionisation in the F_2 layer of the upper atmosphere (at a height of about 300 km.), by means of radio-waves reflection, indicate that during magnetic storms there is often a reduction in the electronic content of the layer. Prof. E. V. Appleton and Miss L. J. Ingram suggest as a possible explanation that the agency responsible for magnetic disturbances heats and expands the atmosphere, thus reducing the electronic density.

Prof. J. Kaplan describes the experimental production of the light of the aurora and the night-sky by means of uncondensed electric discharges through nitrogen. Slight traces of hydrogen prevent the characteristic nitrogen afterglow with auroral spectrum. This fact, together with the absence of hydrogen lines in the spectra of the aurora and the night sky, suggests that hydrogen is absent in the upper atmospheres at the level where those phenomena occur.

Prof. Karl Pearson states that, in general, laws of Nature are neither true nor false, but merely more or less good 'fits' to our observations of Nature. He maintains that statisticians can only state that a hypothesis is false when the P, χ^2 square gives $P = 0$. As an example, he applies the P, χ^2 test to the data recently given by Sir James Jeans for the observed and calculated eccentricity of binary stars, and shows that the theory of equipartition gives a poor fit, if all the binaries are considered.

Contrary to Dr. Baker's view, J. van Zuylen considers that when making stereoscopic photographs the axes of the cameras can be either parallel or convergent to the object. The convergent method does give, however, a larger stereoscopic field of view. Dr. Baker admits that true stereoscopic views may be obtained with parallel cameras if the photographs are mounted so that corresponding points are nearer than the interpupillary distance; otherwise, as is usually the case, a wrong impression is conveyed.

Three new bands in the Raman spectrum of light scattered by heavy water are described by R. Ananthakrishnan, who infers that heavy water is polymerised in a similar way to ordinary water.

The velocity of diffusion of heavy into ordinary water has been measured by M. Temkin, and the diffusion constant is found to be of the usual order of magnitude, contrary to results previously announced by W. J. Orr and D. W. Thomson.

The antirachitic effect in chicken of vitamin D obtained from liver and body fat of various (mostly marine) animals has been compared by Dr. Ottar Rygh. No differences were observed between them.

Experiments with bats infected with *Trypanosoma equiperdum*, a parasitic organism causing venereal disease in horses, carried out by N. Kalabuchov and L. Levinson, show that if the animals are kept in ice boxes at 10° C. or 3° C. for 3–5 days immediately after the infection, the micro-organisms disappear from the blood and the animals recover. Infected controlled animals kept at ordinary temperature die within 9–13 days.

Prof. W. Neilson Jones records experiments pointing to the presence of chemical regulators of plant growth, such as ethylene, in certain organic soils. Such constituents of the soil atmosphere may exercise an important influence on the rapid acquirement of an effective root system on the part of seedlings.

Research Items

Culture Sequence in Nebraskan Archæology

MR. WILLIAM DUNCAN STRONG, in a survey of the archæology of Nebraska (*Smithsonian Misc. Collect.*, 94, 10) puts forward a chronological classification of the indigenous cultures of that state and of northern Colorado, in which the primary basis of division is historic, protohistoric and prehistoric. The evidence, apart from documents and European associations in the historic period, is based on the evidence from stratified sites or association with an extinct fauna or geological deposits of pre-recent date. The *Historic Period* covers the occupation by Pawnees, sedentary Sioux, Dakotas, Arapaho and Cheyennes. The Pawnees' occupation is the oldest known of these, extending back into the *Proto-historic Period* (1540–1682). This is the period of highest Pawnee cultural development. The *Prehistoric Period* (1541 back to an undefined past) in its latest phase is characterised by two main cultures, the Nebraskan and Upper Republican, which exhibit certain affinities, but at the same time appear to have maintained their integrity. The Nebraskan covers the area later occupied by the intrusive Siouan. The Upper Republican may be ancestral to the Pawnee, which would thus bridge the gap between historic and prehistoric. Stratigraphical evidence suggests that the Stern Creek culture is older than either Nebraskan or Upper Republican; but it may be an intrusive trans-Missourian culture. Of stratified sites, that at Signal Butte exhibits three phases, of which the third and last appears to be a sub-type of the Upper Republican. Phases ii and i have no pottery; but, throughout the three phases, the development of the projectile stone point, and in a lesser degree other stone implements such as the knife, can be followed in a cultural and chronological progression, which affords argument for linking Signal Butte I, though later, with the Folsom point and recent discoveries on the Lindenmeier site in northern Colorado (see p. 535 of this issue). At present, palæontological evidence is scant and the associations of implements with extinct fauna are culturally too meagre to afford ground for inference.

Stone Implements from South Australia

MR. WALTER HOWCHIN, who went to Australia in 1881 with an interest in prehistoric archæology inspired by association with Canon W. Greenwell, began to collect and study the stone implements of the extinct Adelaide tribe, which previously had been entirely neglected, in conditions which have now vanished. A paper prepared by him in 1893, but not then published in full, has now been completed and brought up to date ("The Stone Implements of the Adelaide Tribe of Aborigines now Extinct." By Walter Howchin. Gillingham and Co., Adelaide, South Australia. Pp. viii + 94. 7*s*. 6*d*.). The implements of the Adelaide tribe were found on the sand dunes of the coastal region near Adelaide and southward to the River Onkaparinga, the most prolific region being comprised within the ancient estuarine limits of the River Torrens. They occur in the recent drift, none having been found in the older formation of the sandhills. In one instance only, at Fulham, have they been found below marine deposits; but these implements must also be described as 'recent'. All stand in a different category from the stone implements of the tableland of Central Australia, with their characteristic desert glaze and ferruginous impregnation. The material most commonly employed for the Adelaide implements is quartzite; but various other rocks were in use, including even the intractable quartz. Flint appears sparingly, some of it being of European origin, imported as ballast. For certain implements, such as 'choppers', a volcanic rock, such as basalt, was employed. Characteristic forms are knives, falling into five classes, chisels, gouges and adzes, hatchets, scrapers (of which eleven varieties are distinguished), points, gravers, borers, etc., as well as a number of microlithic forms. Examples of the magical stones, which figure in aboriginal belief, some of curious form and unknown significance, are included in the collection. As a geologist, Mr. Howchin finds no evidence of a stone culture in any other than 'recent' conditions.

Life-History of the Organism of Pleuropneumonia

IN a former issue of NATURE (Feb. 24, 1934, p. 296), Dr. J. C. G. Ledingham's researches upon the causal micro-organism of pleuropneumonia of cattle were summarised. The matter has been carried a stage further by A. W. Turner (*J. Pathol. and Bacteriol.*, 41, No. 1, 1). He has studied the life-cycles and morphology of this organism in the living state by means of dark-ground observation of macro- and micro-cultures in a new fluid medium, which consists essentially of a peptic digest of ox liver and muscle, enriched with ox serum, and sterilised by filtration instead of by heat. The microbe is not filterable in the strict sense, though there is constant and early production of filter-passing forms ('conidioids'). It typically and constantly forms a relatively enormous branching mycelium, filaments of which may reach a length of 190 μ. It possesses at least five methods of reproduction, for which the term 'genethodes' is suggested. A new order Borrelomycetales to include it and the closely related organism of agalactia is proposed. The suggested terminology is *Borrelomyces* (nov. gen.) *peripneumoniæ*.

Morphology of the Wheat Joint-worm Gall

THE morphology of the stem galls produced on wheat by the chalcid wasp *Harmolita tritici* forms the subject of a paper by Messrs. W. J. Phillips and F. F. Dicke (*J. Agric. Res.*, 50, No. 4; 1935). It appears that the female insect selects for oviposition the upper side of a node, in tissue that will later form an internode. The ovipositor is inserted slightly below the meristematic region, at the union of a leaf base with the stem. The egg is actually deposited in or near the phloem of the vascular bundle. The gall tissue arises partly from the phloem, but mainly from the parenchyma. There is no pith cavity in the part of the internode within the gall area, this section of the internode being filled with gall cells. Practically all the vascular tissue is destroyed in this region, and this inhibits the normal functions of the plant. The entire galled region lignifies and becomes hard by the time the larvæ are fully grown. The gall stimulus seems to be the products of larval

tabolism together with, perhaps, mechanical tation. Unhatched eggs remain inert, a fact ich strongly indicates that no stimulating sub- nce is injected into the tissues at the time of position to initiate gall-formation. The absence the insect over the immense wheat area of Kansas d western Missouri seems to be due to the fact at the meristematic zone at the node of the wheat this region is too tough and hard for oviposition. is suggested that by fertilisation, or otherwise, e growth of the wheat might be brought to a stage suitable for the insect at the normal time of attack.

frigerated Gas Storage of Apples

LEAFLET No. 6 on Food Investigation, by Drs. anklin Kidd and Cyril West, issued by the Depart- ent of Scientific and Industrial Research, 1935, ows how completely scientific investigation has now tablished suitable conditions for winter storage of e apple crop. It is now clear that if both the mosphere surrounding the apples and the tempera- re are controlled, very adequate storage conditions n be provided when certain precautions are taken. ontrol of the atmosphere enables the oxygen supply be cut down, and the carbon dioxide supply, eleased by the respiration of the apples, to be main- ained at a suitable level. Whilst the slower respira- ion doubles the lifetime of the apples in store, the arbon dioxide has further influence in retaining the riginal green colour and hardness of the fruit. The emperature of the store is cooled as rapidly as ossible to about 40° F. and kept about this level— oo high for the development of the low-temperature reakdown conditions which so frequently follow when the fruit is released from stores at freezing emperatures. One of the most significant lessons earnt in recent years is the influence of the volatile roducts released from ripening fruit in producing urther and deleterious changes in the fruit. They re controlled largely by their absorption by wrapping the fruit in paper soaked in mineral oil; it is also now clear that varieties with different ripening periods should be stored separately, as these substances are released in greatest quantity just as the apples begin to ripen. Practical details as to the construction and management of gas storage containers are given in this very concise publication.

Problems of Cacao Cultivation

1935 marks the close of the five year Cacao Research Scheme which has been carried out at the Imperial College of Tropical Agriculture, Trinidad, and a summarised account of the present situation has been published by Sir Geoffry Evans in *Tropical Agriculture*, 12. The work, financed jointly by the producers and manufacturers themselves, was launched as the first organised attack on the botanical and soil problems that arise in the cultivation of the crop. The aim of the botanical researches has been defined as "the collection of information necessary for improvement of both yield and quality", a uniformity of production, at least locally, being specially desirable. Improved yield will then justify intensive cultivation, which in its turn will be limited to the more productive areas. Selection and propaga- tion studies have, therefore, been the chief lines of work, the development of good methods of vegetative propagation being of particular importance as only by this means can uniformity be obtained, cacao being subject to cross-pollination. As regards chemical and ecological researches, systematic studies of 'good' and 'bad' cacao soils have been made and detailed surveys of soils in representative cacao-growing districts carried out. From such investiga- tions, it is now possible to state whether or not a particular soil will prove suitable for profitable cacao production, fluctuations in soil and atmospheric moisture being a factor of some importance. Further, manurial studies have shown that both the quantity and quality of the product may be greatly improved by the addition of suitable fertilisers. For a more detailed account of the scientific side of the work, reference should be made to the four annual reports on cacao research already issued and obtainable on appli- cation to the editor, *Tropical Agriculture*, Imperial College of Tropical Agriculture, Trinidad, B.W.I.

Research at the Bose Research Institute

PAPERS recording the biological and physical researches, under the direction of Sir J. C. Bose, at the Bose Research Institute, Calcutta, have recently been published collectively ("Transactions of the Bose Research Institute, Calcutta", 9, 1933–34: Biological and Physical Researches. Edited by Sir Jagadis Chunder Bose. London, New York and Toronto: Longmans, Green and Co., Ltd., 1935. 18*s*. net). Further work on the physiology of *Mimosa pudica* has been carried out, during which the effect of flowering on diverse internal activities, especially of that of the pulvinus, were examined. The appear- ance of the inflorescence induces a depression in the moto-excitability of the pulvinus. This investigation, together with others, such as a study of variation in longitudinal and diametric growth in *Helianthus*, and the determination of the actual moment when germination commences inside a seed, together with the measurement of the rate of growth of the embry- onic radicle, makes use of the continuous automatic record method which is so closely associated with the Bose Research Institute. By automatically recording the rate of oxygen consumed during respiration, a respirograph devised at the Institute is claimed to be very accurate and sensitive. This apparatus is fully described and illustrated. An investigation has been carried out on the physico- chemical and physiological nature of fat-soluble vitamins of *Cicer arietinum*, a pulse commonly used throughout India as an article of diet. The oil of certain varieties approaches cod liver oil in vitamin efficiency. Other researches at the Institute during the year under review include an anthropological study of the primitive Oraons of the Ranchi district, the continuous emission spectra of the hydrogen halides, and the flame spectrum of HCl.

Geology of Ceylon

So little has been published about the geology of Ceylon, that a monograph on the subject, accom- panied by an excellent geological map, by J. S. Coates, who until recently was Government mineral- ogist of the Island, is particularly welcome (*Ceylon J. Sci.*, B, 19, 101–187; 1935). In order of age the formations described are as follows: Bintenne Gneisses are specially developed in the low country of the south-east. Khondalite series of granular quartzites and other metamorphic rocks, including garnet-sillimanite schists, form the central mountain system of the Island. Charnockites are extensively developed as sills in the Khondalite series and also occupy the whole of the south-western part of the

Island. There they are associated with garnetiferous leptynites that are regarded as sheared portions of charnockitic rocks. In the north and north-west a later series of Wanni Gneisses and granulites occur. The younger Pegmatites are of two types : a white variety (Balangoda group) remarkable for its variety of accessory minerals, including zircon and radioactive minerals ; and a red variety poor in these accessories. Dykes of dolerite, peridotite and pyroxene-scapolite rocks also occur. Nine-tenths of the Island are occupied by the above crystalline rocks. The remaining deposits include the Jurassic Tabbowa Series ; Miocene and related Tertiary beds ; and Pleistocene and Recent coastal deposits and river alluvium, the last of which include the gem gravels for which Ceylon is famous. Gem-corundum has been traced only to the white pegmatites which are also the source of beryl, chrysoberyl, topaz, tourmaline and zircon. Moonstone occurs in bands of a sheared quartz-felspar rock probably related to the pegmatites.

Ionisation of the Upper Atmosphere

E. V. APPLETON and R. Naismith (*Proc. Roy. Soc.*, A, July) have published the results of a long, systematic investigation of the reflection of wireless waves in the ionosphere. The method employed is to vary the frequency of a wave sent upwards, and to plot automatically the delay time of the reflected wave observed at vertical incidence against the frequency. At critical frequencies, the wave breaks through a lower reflecting layer and is reflected at a higher one, and the critical frequency for a given layer is connected with the maximum electron concentration in the layer by a formula which is now well established. The investigation was mainly concerned with daytime conditions, which are more complicated than those observed at night, for instead of the simple E and F regions of ionisation there is frequently an intermediate region E_2 lying above E_1 and a region F_1 lying below the main F_2. The F_1 region is prominent only in summer. The seasonal variations of the noon values of ionisation in regions E and F_1 agree with a theoretical calculation based on the assumption that direct solar radiation is the ionising agent and recombination of ions the predominant dissipative process. The diurnal and seasonal variations of region F_2 are quite different, the critical frequency for summer noon being slightly less than for winter noon. The authors reject the conclusion of some of the American workers, that critical-frequency determinations do not give a true measure of the electron concentration ; and explain their results on the assumption of a high molecular temperature for the upper atmosphere at summer noon. This causes a reduction in the electron concentration. The temperature required is of the order of 1,200° K., and could be due to molecular dissociation, or to collisions of excited molecules. The anomalies connected with region E are less fully considered, but examples are given of a special type of region E condition, common in summer, in which a thin stratum is formed which reflects strongly at both upper and lower surfaces, and which may give good reflection and hence very favourable transmission conditions for quite short waves.

Interaction of Neutrons with Matter

T. BJERGE and C. H. Westcott (*Proc. Roy. Soc.*, A, July) have investigated the production of 'slow' neutrons by the passage of neutrons through hydrogen-containing substances. Their main experiment consisted in surrounding a radioactive neutron source with cylindrical vessels of water of varying diameter, and measuring the artificial radioactivity induced in a specimen placed outside the vessel. The curves show a maximum effect for a thickness of water of about 10 cm., and further experiments show that the 'fast' neutrons coming from the source are reduced to half-value in about 7 cm. of water while the 'slow' ones only have a half-value distance of about 1·6 cm. The scattering cross-section of several atomic nuclei for 'slow' neutrons was estimated ($3 \cdot 10^{-23}$ cm.^{2} for hydrogen, 3×10^{-24} cm.^{2} for carbon and oxygen). The cross-section for absorption varies very much from element to element—it is about 4×10^{-25} cm.^{2} for oxygen and $1 \cdot 2 \times 10^{-21}$ cm.^{2} for boron. J. R. Dunning, G. B. Pegrum, G. A. Fink and D. P. Mitchell (*Phys. Rev.*, Aug. 1) have also studied these neutrons. Their results agree approximately with Bjerge and Westcott in giving a halving-distance in water for fast neutrons from a radon-beryllium source of about 8 cm., and a maximum production of slow neutrons by spheres of 10 cm. radius. These workers have also studied the production of slow neutrons in heavy water, and they find that it is about 5·5 times less effective than ordinary water. They conclude that there is a smaller probability of interaction between a neutron and a deutron than between a neutron and proton, and this is borne out by absorption experiments. The collision cross-section of a number of elements was measured for fast and for slow neutrons—the former shows a fairly regular increase with atomic number, while the latter varies violently from element to element, and attains a value 3×10^{-20} cm.^{2} for cadmium. The high absorption of cadmium for slow neutrons was found to be nearly exponential when measured with a parallel beam, and was also found to be a true absorption associated with very little scattering.

Structure of Keratin

ASTBURY and his co-workers have shown that the molecular structure of keratin is such that the 'extended' form β-keratin consists of flat grids of atomic chains bound together by side chains. A number of such grids piled on one another form the β-keratin crystallites, and a characteristic spacing of about 4½ A., found from the X-ray photographs of keratin structure, is supposed to represent the distance between the grids, while a spacing of 9½ A. represents the distance between main chains in the plane of the grid. In the normal unstretched α-keratin, the main chains are regularly folded in planes perpendicular to the grid. In a recent paper (W. T. Astbury and W. A. Sisson, *Proc. Roy. Soc.*, A, July 1), this view receives rather direct confirmation. Specimens of horns and hair were squeezed laterally in the presence of steam. The α-keratin was first changed to the β-form and the β-keratin crystallites then took up a definite orientation, X-ray examination now revealing directly that the 4½ A. spacing and 9½ A. spacing were respectively normal and parallel to the flat surface of the squeezed specimens. The sharpness of the X-ray diffraction spots shows that the keratin grids are not very wide, but that many of them are piled on top of one another to form the β-keratin crystallite. The end of the paper contains a short discussion of the evolution of fibrous proteins, and speculates on the condensation of these from the globular protein structures.

Association of Special Libraries and Information Bureaux

THE twelfth annual conference of the Association of Special Libraries and Information Bureaux, held at St. John's College, Cambridge, on September 20–23, was of more than usual interest to those concerned with the use and dissemination of scientific and technical information of all kinds. In his presidential address on "Interpretation of Science" Sir Richard Gregory referred to the neglect of scientific material to-day by writers of all kinds, as compared with writers of the nineteenth and earlier centuries. Science needs, he pointed out, not only writers to make its achievements intelligible to general readers, but also poetic and other interpreters who will expound its intent and influence by artistic representation or performance. Poetry, like other forms of art, should follow on the heels of knowledge, and Sir Richard quoted examples of the expression of observations of Nature and science in classical literary style, as well as of the poetic interpretation even of mechanised science. Literary genius has as yet rarely found inspiring themes in the great achievements of modern science, and, until this is done, the full appreciation of science and its achievements by mankind would be wanting.

This appeal for the creation of a new school of poets of science who employ their genius to interpret scientific truths with accuracy and genius was fully in harmony with the two major themes of the Conference. The first of these was a symposium on "Special Libraries and Their Problems", covering questions concerning the recruiting, training and future possibilities of special library staff. The discussion was opened by a paper by Mr. J. D. Cowley, on "Training for Special Library Work", who described the training given at the London University School of Librarianship, of which he is director, and the modification of its syllabus to overcome the practical difficulties experienced. Regarding librarianship as including "sympathetic and informed aid in the interpretation of material for study and research", the training aims at providing men and women who are not only trained in the technicalities of handling the material of research, but are also sufficiently informed in the subject of that material to interpret it and pass on the information gained in an acceptable form to others. The question whether training in librarianship should precede or follow training in research has yet to be decided, and some difference of opinion on this point was revealed in the subsequent discussion. Mr. Cowley's remarks about deficiencies in linguistic ability in graduates seeking admission to the course were endorsed in the subsequent discussion from experience in recruiting for information service. Mr. Cowley remarked that the School of Librarianship has so far failed to attract the really first-class science man.

Mr. Cowley's paper was followed by others on the "Functions of a Technical Information Bureau", by Dr. E. S. Hedges and Dr. C. E. Homer, who described the work of the Bureau of Technical Information of the International Tin Research and Development Council, and by Mr. F. H. Smith. Mr. B. Fullman, information officer of the British Non-Ferrous Metals Research Association, discussed "Information Work as a Career for the Scientist" and pointed out the possibilities in such work for a man of first-class training and originality. The success of information work and the rewards accruing from it are largely dependent on the personality of those engaged in it, and a similar view was expressed in a paper by Mr. T. M. Herbert, research manager of the London, Midland and Scottish Railway.

The second major theme of the Conference related to co-operation between industry and the public library services. Opening this discussion on September 22, Mr. R. Brightman, of Imperial Chemical Industries, Ltd., pointed out that the possibilities in this direction are only just beginning to be appreciated with the growth of special libraries in industry itself. The organisation of such internal library services is an essential preliminary to co-operation with external organisations, and Mr. Brightman then indicated some of the ways in which co-operation has already proved possible and further possibilities in which co-operation would lead to the more effective use of existing resources. Other constructive suggestions were made by Miss E. W. Parker, of the Mond Nickel Co., Ltd., in a review of the use made by industry and commerce of the public libraries in the London area, while Mr. J. P. Lamb described the progress of co-operation between local industries and the public library services in Sheffield. The value of personal contact between industry and the public librarian was emphasised both in these papers and in the discussion which followed.

Following on a paper on the new University Library on September 21, by Mr. H. C. Stanford, secretary of the library, members of the Conference visited the new University Library building. In the afternoon, Sir Stephen Gaselee gave a valuable paper on the "Libraries and Sources of Information in Government Departments", including descriptions or notes on the chief libraries represented in the 'Circle of State Librarians'. Sir Stephen Gaselee testified to the willingness of the Foreign Office library and other departmental libraries to deal with private inquiries, so far as facilities permit.

The annual report of the Council presented to the annual meeting indicated a slight increase in membership, but the necessity for an augmented income, if the work is to be developed adequately, was emphasised. Reference was made to the inauguration of a scheme for the issue of a quarterly list of recently published scientific and technical books, each book recommended by an expert qualified to judge the book in question. The list is intended mainly for the guidance of public and general librarians. During the year, a London and Home Counties branch was inaugurated, several meetings of which have already been held.

Other papers read before the Conference included one on reference books and their use, by Mr. B. M. Headicar, which dealt particularly with lesser-known books of this type, an account of the work of the Council for the Preservation of Business Archives by Mr. A. V. Judges, its hon. secretary, and an admirable analysis by Mr. R. S. Lambert of the response to information of all kinds supplied in the broadcasting services.

Possible Bearing of a Luminous Syllid on the Question of the Landfall of Columbus

By L. R. Crawshay, Marine Biological Association Laboratory, Plymouth

IN a paper by Lieut.-Comdr. R. T. Gould on the "Landfall of Columbus"[1] the author, after reviewing the whole subject, follows Murdock (1884) in placing the landfall at Watling's Island, the second island, Santa Maria de la Concepcion, being identified as Rum Cay, and the third, Fernandina, as Long Island, with Clarence Harbour as the harbour of entry on the east side of it. In the course of the discussion, he refers to the unexplained incident of the mysterious 'light' recorded by Columbus, as seen by him and others from the poop of the *Santa Maria* at about 10 p.m. on the night of October 11, 1492, "i.e., about four hours before making the landfall, and an hour before moonrise". The light was seen "some distance away in the darkness. It is described as looking like the flame of a small candle, alternately raised and lowered. It seems to have gone out of sight again not long after". The author proceeds: "Judging by the speed of the ships, as given in the journal for the night, the light must have been some 35 miles or so eastward of the landfall, and well to windward of it".

At such an estimated distance eastward of Watling's, the position of the light would be well out into the Atlantic, in some 3,000 fathoms of water, where the presence of a native canoe accounting for it, as suggested by Markham, seems inconceivable. Scarcely more credible is the view expressed by Mackenzie (1828), who makes the landfall at Cat Island, assuming the light to have been a shore light at Watling's, the island itself, however, being missed by Columbus in the darkness. Murdock disposed of the difficulty by the extreme course of suggesting that the light was non-existent and imaginary. Against the latter surmise is the definite record, not only of the light, but in such detail and in such circumstances as strongly to support the view that it was due to a surface display at the time of luminous marine annelids of the genus *Odontosyllis*.

In the case of *O. enopla*, Verrill, of which the habits and structure were described by Galloway and Welch[2], the times of the luminous displays, associated as they are with the reproductive process, appear to have some relationship with the lunar phases, and in one case observed definitely with the third phase, though the whole causes controlling the time of occurrence are somewhat obscure, with approaching dark and low tides apparently two chief contributing factors.

In the Bahamian species of *Odontosyllis*, frequently observed by me through past years, while engaged on the Sponge Fishery Investigations for the Colonial Office, the date of occurrence of the displays, though variable, was always closely associated with that of the moon's last quarter. In a single case, among seven definitely recorded occasions, a maximum interval amounting to about 3½ days was probably explainable by approaching disturbed weather, at the time occasioning premature appearance of the females at the surface. In other cases, the time was usually within about twenty-four hours of the moon's last quarter, the average being about eighteen hours. Examination of some preserved material remaining of this species, though at present undetermined, and possibly not yet described, shows it to be clearly distinct from the Bermudian species, and especially, among other features, in respect of its fusiform-clavate and articulated swimming setæ of the parapodia. Further, unlike the Bermudian species, as likewise also to some extent a British Honduras species, structurally similar to, if not identical with *O. enopla*, the time of appearance does not coincide with approaching dark, but may be long after darkness has closed in, the latest definitely recorded time being 8.30 p.m. The period of illumination is always very brief, usually not exceeding 5–10 minutes from first to last, and often so short as barely to allow time for a specimen to be captured. It may perhaps be repeated on a following night, but more usually will not recur until the same phase of a subsequent lunation. The illumination does not occur in all months, but has been definitely noted by me, between 1921 and 1923, in January, April, May, July, October and December.

The purpose of these luminous displays, in the species concerned, is wholly associated with the reproductive process. In his description of the swarming of *O. phosphorea*, Moore, observed by him at Nanaimo, British Columbia, Potts refers[3] to somewhat indiscriminate mixing of males and females, and the regularity of the times of mustering, and in increasing numbers, of both sexes, about half an hour before sunset. He expresses surprise concerning the difference of habit in *O. enopla*, in which the whole circumstances show a direct attraction of the males, through the illumination, by the females individually, for fertilisation of the ova as extruded. This is precisely what occurs in the Bahamian species. 'Swarms', strictly speaking, cannot be said to occur. But a varying number of mature females, ranging on occasions from perhaps half a dozen to twenty or so in a given location, will appear suddenly and almost simultaneously; a stream of brilliantly luminous matter is emitted by each one of them with the extruded ova, probably two or three times repeated at short intervals; and with this as a signal a number of males rush in, with short intermittent slight flashes, towards the light for fertilisation, partly with attachment to the female, partly darting rapidly to and fro through the luminous trail. Thus the whole process is concentrated within a brief interval of time, and more usually, as it seems, completed on one night, for a particular moon. This period of the lunar month is no doubt particularly favourable for the darkness it affords at a suitable time of day within a few hours after sunset. Whether directly influenced by the moon or not, it is very remarkable that, so far as I am aware, the displays on the part of the females never occur through the long and dark period immediately following the last quarter, or until the next lunation, which again may be missed until the same phase of a subsequent one.

With respect to the comparison of the light, in the journal of Columbus, with "the flame of a small candle alternately raised and lowered", and its disappearance soon after, the illuminating display of a single *Odontosyllis* female will at such times usually show this feature of separate short periods of excessive and declining brilliance, repeated two or three times over, or more. From the poop of the *Santa Maria*, it is easy to believe that this light would be visible on a dark night up to 200 yards, or even farther, away. As probably as not, the strange and unaccountable light would disappear almost as soon as there was time to report it.

As observed at Abaco, and within a limited area, the species concerned ordinarily frequents grounds of shallow water, and up to about 2 fathoms in depth, though probably extending much outside this. The displays, though variable in time, usually occur about the time of low water, or within an hour, or occasionally as much as 2½ hours, on either side of this. If the light was seen by the *Santa Maria* about 10 p.m. on the night of October 11, and the moon rose an hour later, as recorded, the moon was then presumably about one day before the last quarter. The time of low water, probably about 7.30–8.00 p.m., is comparatively unimportant, considering the variability in the time of appearance of the syllid in this respect. The latest time of display definitely noted by me in examples at Abaco was 8.30 p.m.

Murdock in his chart, followed by Lieut.-Comdr. Gould, shows the course of Columbus passing round the south side of Watling's Island. Mackenzie, who makes the landfall at Cat Island, shows it on the north side. In the latter case, there is a large shallow bank, with rocky heads, extending out for some 3½ miles from the present low-lying northern shore of the island; a position near the northern point of this bank, as shown in the chart of Mackenzie with indication of the position of the light, would leave little difficulty in explaining not only the presence of the Syllid as the source of the light, but also the passing of the island unobserved in the darkness at such a distance. At or near the extreme northerly point of this inner bank, there is little cause to doubt that the ships may have passed without striking or even sighting any submerged reef head, if then here existing.

As against the estimated distance of the position of the light at some thirty-five miles or so eastward of the landfall, and considering the frequent difficulty found in reconciling distances recorded with those existing between positions, as interpreted in the itinerary, it is on the whole a remarkable coincidence in the present connexion that the distance from the northern bank of Watling's to the south-east point of Cat Island is about 43 miles.

The primary purpose in the present discussion is to direct attention to a very probable explanation of the mysterious light observed on the night before the landfall was sighted, hitherto without any satisfactory explanation suggested, and thus leaving inevitably a weak point in the data employed for conclusions so reached regarding the identity of the landfall. The inference that it was Cat Island has its own difficulties, the greatest of these being, as it seems, its distance as recorded, about 18 miles, from the second island, while assuming the latter to have been Rum Cay. In any circumstances, I am unable to see how the incident of the recorded light can be regarded otherwise than as a point of evidence of first importance towards settlement of the problem.

National Water Resources

THE joint committee of Lords and Commons, appointed to consider and report on measures for the better conservation and organisation of water resources and supplies in England and Wales, held an inquiry during the month of July last, and completed it for the time being. The evidence given before the committee with a report of the proceedings, after being tabled in the Houses of Parliament, has been published*. The findings of the committee are set out in six resolutions, the first of which, affirming that the aggregate available supply of water is ample for all anticipated requirements of the country is, at least, reassuring, and should dispel whatever doubts (if any) have been entertained on this score; though it is little satisfaction to those who have experienced the serious inconveniences of the recent drought to know that, while locally there has been scarcity and restriction, elsewhere supplies have been plentiful and even running to waste.

The real crux of the situation is contained in the second resolution, which admits that a number of problems of distribution, compensation and similar matters are outstanding, and should be dealt with without delay. Taken in conjunction with the third finding, that sufficient material and experience is possessed by the Ministry of Health to enable the legislation necessary to deal with the problems to be drafted, there is a distinct implication that the Ministry of Health has been remiss in not coping with the difficulty before. Indeed, the main trend of examination by the committee of a departmental witness went to show that the former considered it was being called upon to discharge a duty which was superfluous, and the reason put forward by the secretary of the Ministry in support of the appointment of the committee was that it was for the purpose of getting the advice of an "impartial and competent" body on points of conflict which were known to exist, but which the Ministry, apparently, had made no direct effort to ascertain or define. Sir Arthur Samuel, a member of the joint committee, expressed himself pointedly if colloquially, when he asked Sir Arthur Robinson, "Are you not asking us to hold the baby for you and do the work which you yourselves ought to do, to shield you?"

It is scarcely surprising, therefore, that the remaining resolutions of the committee should call for the

* Joint Committee on Water Resources and Supplies (Session 1934–35). Vol. I, Proceedings of the Committee, 2*d.* net; Vol. II, Minutes of Evidence, together with an Appendix, 3*s.* 0*d.* net. (H.M. Stationery Office.)

preparation by the Ministry of Health of a preliminary memorandum on matters of controversy, to be circulated to all parties likely to be interested, in order to enable evidence in criticism to be heard after the recess, the committee feeling that, until the issue of such a memorandum, no useful purpose could be served by hearing further evidence on the subject-matter before them. The absence of any witnesses to speak on the industrial side of water user was, in fact, the outstanding feature of the inquiry, so far as it has gone, and it rather seems to indicate that trade and industry have been ignored by the Ministry in the prosecution of its plans. The unwisdom of such a step is surely obvious in connexion with "a question which raises interests very much wider than the interests of the Ministry of Health".

Road Width and Accidents

THE cause of road accidents is a topic which gravely concerns every class of the community, and each attempt to determine the degree to which any one factor operates in promoting road safety deserves general attention. From the point of view of safe driving, it is probable that there is an ideal width of road for each set of traffic conditions and that, at a certain traffic density, the division of the roadway into separate 'up' and 'down' tracks becomes advisable.

It is of interest, therefore, to read in *Roads and Streets* (Chicago, July 1935) a paper submitted to the Highway Research Board by Prof. R. L. Morrison, of the Department of Highway Engineering at the University of Michigan, entitled "Effect of Pavement Widths upon Accidents". The main object of the author's investigation was to find evidence bearing upon the desirability of building 20 ft. roadways instead of the smaller widths which had been adopted as adequate to allow of the passage of two vehicles. It is obviously difficult to make a rigid comparison in figures between any two roads, equal or unequal in size, and this is intensified by the uncertain data obtainable regarding many accidents, and by the absence of figures relating to minor unreported accidents which might yield valuable evidence.

In this investigation, several portions of roads are dealt with, and figures are given regarding (*a*) 34 miles of 20-ft. roadway and (*b*) 19 miles of 18-ft. width. After eliminating those unrelated to road width and found to occur at the rate of (*a*) 1·06 and (*b*) 0·90 accidents per mile, the author finds that those which are affected by road width occur at the rate of (*a*) 1·00 and (*b*) 1·70 per mile. This last figure on being adjusted in order to obtain a comparison on a common basis is increased to 2·20, but here the reasons given are not quite convincing, though they may be justified by a personal knowledge of the roads and their conditions. If, however, we take from the detailed analyses given in the paper the figures for accidents which can be accounted to grossly careless driving—the main cause of preventable accidents—the rates are (*a*) 0·53 and (*b*) 1·10.

These figures strikingly support the final comparison ratio deduced by the author, whose conclusion is that, on the grounds both of the accident rate and on the relative costs, of which figures are adduced, the 20-ft. roadway is justified. The author agrees that his data are not sufficiently extensive for general conclusions to be drawn, but suggests that the method of analysis might be adopted as a general approach to the problem. The figures dealt with are understood to relate to the accidents occurring in one year.

Biological Effects of Different Regions of the Spectrum

AT the red edge of the invisible in the spectrum there is a narrow band of light waves which have a powerful and hitherto unsuspected biological inhibitory effect. This is reported by Lewis H. Flint, of the Department of Agriculture, and E. D. McAlister, of the Smithsonian Institution (*Smithsonian Misc. Coll.*, **94**, No. 5, June 24, 1935), as a result of further studies of the germination of dormant lettuce seeds when exposed to radiation.

Previous studies by Dr. Flint had demonstrated that such seeds could be made to germinate by exposure to red, orange and yellow light; and inhibited from germinating by irradiation with green, blue and violet light. The inhibitory effect was general for this upper end of the visible light spectrum, but reached its greatest intensity at wave-lengths of about 4200 and 4800 A. in the blue-green region.

The discovery of an inhibitory wave-band at the red end of the spectrum which, so far as the germination of lettuce seeds was concerned, was more powerful in its effects than the entire green-blue-violet end of the spectrum, came as a complete surprise. This band lies around the critical wave-length of 7600 A., at just about the point in the red where light ceases to be visible to the human eye.

Ordinarily its effect would be masked by the stimulating effect of the wave-lengths surrounding it, especially in sunlight. Perhaps fortunately for vegetation—although the inhibitory influence has been demonstrated only with lettuce seeds—the solar radiation in this neighbourhood is greatly reduced, owing, it is believed, to its absorption partly by oxygen in the atmosphere of the sun and partly by water-vapour in the atmosphere of the earth. Notwithstanding this absorption, however, the energy of solar radiation at this point is large.

Further studies of the possible effectiveness of this region in respect to the germination of other seeds and in respect to other phases of light sensitivity are now in progress.

Educational Topics and Events

ABERDEEN.—The King has been pleased, on the recommendation of the Secretary of State for Scotland, to approve the appointment of Prof. E. W. Henderson Cruickshank, professor of physiology in Dalhousie University, Halifax, Nova Scotia, to be regius professor of physiology in the University of Aberdeen, in succession to the late Prof. J. J. R. Macleod.

FOR London school-teachers, the London County Council offers an extensive and attractive programme of winter evening lectures and classes designed to bring them into touch with the latest developments in educational methods and to give them opportunities of hearing leading authorities in various branches of learning and on current questions of public importance. A glance through the recently issued handbook for the session 1935–36, giving full particulars of nearly a hundred items, leaves the impression that this scheme, which is self-supporting and obtained last year 13,000 entries, cannot fail to raise the standard of liveliness of school teaching in the metropolis. Of the courses grouped under the heading Science, nearly all deal wholly or in part with the science of life. They include a Saturday morning series at the Zoological Gardens on "Animals at the Zoo", lecture-demonstrations at the London School of Hygiene on "Fundamentals of Biology", a series on the conduct in the school of observations and experiments on plant and animal life, lectures on food and food values, on the teaching of hygiene and on science for senior schools. The last-mentioned course will direct attention to the desirability of framing science syllabuses on a wider basis than that traditionally employed, and will include an exposition of schemes of work which have been found suitable for senior children of both sexes in a London school.

SECONDARY schooling for all is an ideal towards the realisation of which the United States has made notable advances. That the ideal is a mischievous one, and that advances towards it have had devastating results, is the gist of a lively diatribe by one of the staff of a Pennsylvanian High School published in *School and Society* of April 13. The public school is declared to have become, to a large extent, a "racket". A large proportion of the students who are promoted willy-nilly into the secondary schools will not and cannot profit by further schooling in any form. This is the opinion not only of teachers of academic subjects but also, emphatically, of shop teachers, whose energies are largely devoted to making the best of the subnormal pupils for whose benefit money is lavished on special apparatus, special textbooks and individually supervised study. If the material is thus unpromising, the quality of the staff available for processing it suffers from the dominance of the doctrinaire in the direction of the teacher training institutions. Here students are being compelled to spend so much of their time learning how to teach that they have little left for mastering the subject matter they are to handle. They are bewildered by the multitude of their courses, many of them obscured with metaphysical subtleties; and they are practically obliged to accumulate further 'credits' by attending vacation courses remote from utilitarian or cultural values.

Science News a Century Ago

London and Edinburgh Philosophical Journal

THE contents of the October, 1835, number of the *London and Edinburgh Philosophical Journal* consisted mainly of reprints of papers read before various societies. These included one by Sir David Brewster on the structure and origin of the diamond, one by Apjohn on a formula for inferring the dew-point from the indications of the wet-bulb hygrometer, a part of C. B. Rose's sketch of the geology of West Norfolk and a paper by Encke on Olber's method of determining the orbits of comets. There was an original communication from C. L. C. Rumker (1788–1862), the director of Hamburg observatory who had served in the British Navy, to Sir Thomas Brisbane on a new method of reducing lunar observations for the determination of the longitude. The number, however, was of more than special interest as it included the first of a series of official reports communicated by the Council and Secretaries of the British Association on the Dublin meeting.

The Entomological Society

AT a meeting of the Entomological Society, held on October 5, 1835, "Various donations of entomological works were announced, including the first number of the splendid 'Fauna Japonica' by Drs. Siebold and De Haan, presented by the authors. Various new members were elected, including Count De Jean and M. Boisduval, of Paris. A communication was received from Mr. E. Doubleday, containing an account of the total destruction of a beehive by a small moth, *Galleria cereana*, the larvæ of which had completely devoured the comb—portions of which were exhibited. Several living cane plants, greatly infested by the cane fly, were exhibited by Mr. J. C. Johnstone, by whom an account was given of the rapid and alarming progress of this minute insect, its ravages extending over two-thirds of the island of Grenada, to so great an extent that plantations which originally made 300 hogsheads did not now make more than eighty or ninety. . . ." (*Athenæum.*)

Sir Charles Bell at the Middlesex Hospital

ON October 7, 1835, Sir Charles Bell wrote to his brother George, "I don't think I have written to you since I began the lectures, establishing a school in the old Middlesex. At least my spirit and devotion to the art and to the institution to which I am attached will not be denied. I have delivered six lectures, such as only long experience and study could have produced. I lecture to some sixty pupils —which for a beginning is as much as we could expect. N.B.—I have received not one guinea from these lectures and expect none. On the contrary I have subscribed £50 as one of the hospital surgeons, £30 as a lecturer. Nevertheless, the main object will be gained—the preserving the hospital respectable. . . . I now return to the cheap and complete edition of my 'Nervous System'."

The Tortoises of the Galapagos Archipelago

ON October 8, 1835, Darwin records: "We arrived at James Island; this island as well as Charles Island, were long since thus named after our kings of the Stuart line. Mr. Bynoe, myself, and our servants were left here for a week, with provisions and a tent,

whilst the *Beagle* went for water. We found here a party of Spaniards, who had been sent from Charles Island to dry fish and to salt tortoise-meat. About six miles inland, and at the height of nearly 2,000 feet, a hovel had been built in which two men lived who were employed in catching tortoises, whilst the others were fishing on the coast. I paid this party two visits and slept there one night. . . . While staying in the upper region we lived entirely on tortoise-meat: the breastplate roasted (as the Gauchos do *carne con cuero*), with the flesh on it, is very good; and the young tortoises make excellent soup; but otherwise the meat to my taste is indifferent."

Societies and Academies

PARIS

Academy of Sciences, August 12 (*C.R.*, 201, 413–436). The President announced the death of Antoine Guntz, *Correspondant* for the Section of Chemistry. HANS SCHWERDTFEGER: Functions of matrices. BORIS KAUFMANN: The infinitesimal properties of closed ensembles of arbitrary dimension. RICHARD BRAUER: The integral invariants of varieties representative of simple closed Lie groups. GEORGES BOURION: The limit functions of the partial sums of an integral series at the frontier of the circle of convergence. MARCUS BRUTZCUS: The appreciation, *a priori*, of the value of a commercial combustible for motors. RENÉ DUBRISAY: The action of sulphur on silver. The blackening of silver can be produced by sulphur without the intervention of a sulphur compound. The increase in the rapidity of the action caused by a high vacuum may be partly due to the increased rate of diffusion of the sulphur vapour, and partly to the removal of a layer of protective gases on the silver. JEAN CALVET, JEAN J. TRILLAT and MILOSLAV PAIČ: The recrystallisation of pure aluminium. Application of the X-ray method to the study of the velocity of crystallisation of aluminium containing 99·9986 per cent of the metal. At 0° C., slight traces of crystallisation appear after 12 hours, and this is still incomplete after 336 hours. At 100° C., recrystallisation is complete after one minute, and at higher temperatures is practically instantaneous. CHARLES DUFRAISSE and MARCEL GÉRARD: Dissociable organic oxides and the anthracene structure. The existence of a photo-oxide of anthracene: its thermal decomposition. According to the theory developed from the study of the rubenes, anthracene should absorb oxygen rapidly under the action of light, forming a compound decomposing on heating but without emitting oxygen. The results of experiments with anthracene are given, fully confirming these views. RENÉ SALGUES: Erythrocytes, hæmoglobin and the globular value in the course of cancerous affections in birds. LÉON VELLUZ: The comparative action of the bile acids on the tetanus and diphtheria toxins: the special properties of lithocholic acid. For the same polycyclic structure, the neutralisation of the diphtheria toxin depends on the number of alcohol groups, whilst this substitution is without influence on the neutralisation of the tetanus toxin. Lithocholic acid is the most energetic agent known as regards neutralisation of the toxin of diphtheria. RAYMOND-HAMET: The non-modification of the sympathicolytic activity of yohimbine by the introduction of a double bond in the molecule of this alkaloid.

August 19 (*C.R.*, 201, 437–460). LOUIS BLARINGHEM: The fertility of *Hemerocallis flava* and of its hybrid (*H. flava* × *H. fulva*). HARALD CRAMÉR: The asymptotic properties of a class of chance variables. G. PÓLYA: Integral series satisfying an algebraic differential equation. PIERRE LEJAY and TSAN HUNG CHI: Gravity map of the south-west of China. REZA RADMANÈCHE: Influence of temperature on the electrical conductivity of quartz. PHILIPPE WAGUET: Light emission of mercury arcs under high pressure. From measurements with a photoelectric cell of the light intensities of a mercury arc at varying incidences it is concluded that the colour of the mercury arc varies according to the direction from which it is observed. This complicates the problem of heterochrome photometry when the mercury arc is used as a light source. GEORGES FLUSIN and CHRISTIAN AALL: The study of the system calcium carbide, calcium oxide. G. DEDEBANT, PH. SCHERESCHEWSKY and PH. WEHRLÉ: The theory of the general circulation of the atmosphere. The law of the rotation and the field of pressure. FERNAND ARLOING, ALBERT MOREL and ANDRÉ JOSSERAND: The action on tumours, in intravenous injections, of soluble chemical products in which iron is associated with vitamin C (ascorbic acid).

LENINGRAD

Academy of Sciences (*C.R.*, 2, No. 9, 1935). L. G. MAGNARADZE: The problem of the elastic oscillation of the semiplane. G. M. BAVLI: A generalisation of the boundary problem of Poisson. N. A. SLIOSKIN: Discontinued two-dimensional movement of an ideal gas round a curved obstacle. N. A. DOBROTIN: Distribution in angle of protons projected by neutrons. M. DIVILKOVSKIJ and M. FILIPPOV: Measurement of the intensity of magnetic fields of very high frequency. W. FRÉEDERICKS and V. ZVETKOV: Orientating action of an electric field on the molecules of anisotropic fluids. M. P. VOLAROVITCH and A. A. LEONTJEVA: (1) Determination of the specific volume of molten diabase at high temperatures. (2) Determinations of the specific volume of molten salts at high temperatures. P. P. PORFIROV: Determination of the capacity of a polarised mercury electrode. N. P. SMIRNOV: The stimulus to precipitation. N. N. VOROZHCOV, Jun. and A. T. TROSCHENKO: Morphine content in the latex of *Papaver somniferum*. A. E. FERSMAN: The *ek* system (see NATURE of August 31, p. 349). S. N. SIMAKOV, N. A. SCHWEMBERGER and O. S. VJALOV: Silurian naphtha in central Asia. N. A. SCHWEMBERGER: Contribution to the problem of the silurian naphtha in Central Asia. M. N. IVANTISHIN: Contribution to the problem of the geochemical zonation in the distribution of metallic elements on the territory of the Far Eastern region. A. G. EBERZIN: The Tchauda layers in the Taman peninsula. O. NIKIFOROVA: The Upper Silurian of Podolia. S. F. CEREVITINOV and L. V. METLICKIJ: Effect of an electric field of high frequency on the keeping qualities of fruit and vegetables. A. V. POPCOV: Note on secondary dormancy of *Taraxacum megalorhizon* seeds. T. S. RASS: Some regularities in the structure of eggs and larvæ of fishes in northern seas.

(*C.R.*, 3, No. 1, 1935). I. M. VINOGRADOW: Some rational approximations. I. D. ADO: Representation of Lieschen groups by linear substitution. S. TCHUNIKHIN: A generalisation of the theorems

of G. Frobenius and of V. Turkin. A. P. DIETZMANN and A. A. KULAKOV: Some criteria of non-simplicity of finite groups. W. FEDOROV: Uniform functions. S. SHUBIN: Application of the method of the Dirac density matrix to the theory of metals. G. LIANDRAT: Utilisation of a selenium photo-element for the measurement of the ultra-violet solar radiation in the region of 3200 A. A. M. STEFANOVSKIJ, E. S. TATARSKIJ and N. V. ZELIAKOV: Dependence of the structure of ammonia catalyser upon the conditions of its reduction. V. G. FESENKOV: Photometric analysis of the luminosity of the night sky. N. S. FILIPPOVA: Isotopes of hydrogen in petroleum. P. LAZAREV: Ionic theory of the physiological action of short waves. A. N. PARSHIN: Extracts from the muscle tissue of dog and rabbit. V. P. NEKHOROSHEV: A find of Upper Palæozoic marine deposits in the Zaisan basin. M. E. NEUHAUS: Data concerning crossing-over between the *X* and *Y* chromosomes in females of *Drosophila melanogaster*. B. K. STEGMANN: Distribution and geographical variation of *Saxicola torquata*.

ROME

Royal National Academy of the Lincei, April 28. G. ROVERETO: The Montenotte series as a constituent element of the Western Alps and of the Apennines. M. RENATA FABBRI: Differentials of higher order. L. ROTH: The regularity of algebraic surfaces. E. CIANI: A sizigetic bundle of cubic surfaces (1). A. DE MIRA FERNANDES: Compound tensorial derivation in non-point spaces. TH. MOTZKIN: Some characteristic properties of convex ensembles. N. W. AKIMOFF: Considerations on propulsive efficiency. C. TOLOTTI: Typical case of dynamic universes endowed with complete symmetry about a centre. The field-equations of a universe showing complete symmetry about a point have been derived previously, the only hypothesis made being the existence of suitable co-ordinates with respect to which the propagation of light is isotropic. Further assumptions now made are that such isotropy holds with respect to substantial co-ordinates (connected with the moving matter) and that, in such co-ordinates, the velocity of light is independent of position. Under these conditions, the gravitational equations are shown to relate necessarily to a completely homogeneous universe. G. PICCARDI: The atmospheres of the planets. A hypothesis is advanced to explain the fact that the atmospheres of the planets near the sun are characterised by oxygen compounds and those of the more distant planets by carbon-hydrogen compounds. T. FRANZINI: The diffusibility of deuterium into metals. The displaceability of occluded hydrogen by an electric field is confirmed, and the absence of a similar effect with deuterium is shown. Further work is necessary to decide whether deuterium is adsorbed, but not absorbed, by palladium; or neither adsorbed nor absorbed; or absorbed, but not displaceable. R. MANZONI ANSIDEI: The Raman spectra of the isomeric nitrotoluenes. The measurements made confirm those published by Kohlrausch, Dadieu and Jele in 1931. G. PICCARDI: (1) The spectrum of neodymium oxide vapour. (2) The spectrum of samarium oxide vapour. C. ACQUA: The nature of ultra-viruses. From a review of the evidence available, the conclusion is drawn that filterable viruses have an auto-catalytic action. A. MESSERI: The organising power of wood and of the primary phloem.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, 21, 507–516, August). E. C. MACDOWELL, M. J. TAYLOR and J. S. POTTER: The dependence of protection against a transplantable mouse leukæmia upon the genetic constitution of the immunising tissue. Two strains of mice were used. Embryonic tissue from one strain induced resistance in all cases; that from the other failed to induce resistance in its own strain; embryonic tissue of hybrids of the two strains are as successful as the first. J. W. ALEXANDER: (1) On the chains of a complex and their duals. (2) On the ring of a compact metric space. ALFRED J. MARIA and ROBERT S. MARTIN: On the representation of positive harmonic functions. M. H. ELLIOTT and W. C. TREAT: Hunger-contractions and rate of conditioning. Hunger-contractions, visible in rats with stomachs transplanted to a position just below the skin, were found to coincide with periods of activity. Rats with such hunger-contractions were able to learn to respond to a conditioned stimulus (an electric light) more quickly than animals which had received food.

Food, Farmer and Future

"Considering *Punch* as the expression of the popular voice . . . is it not also surely some overruling power in the nature of things, quite other than the desire of his readers, which compels him, when the squire, the colonel and the admiral are to be at once expressed, together with all that they legislate or fight for, in the symbolic figure of the nation, to represent the incarnate John Bull always as a farmer—never as a manufacturer or shopkeeper and to conceive and exhibit him rather as paymaster for the faults of his neighbours, than as watching for opportunity to gain out of their follies."—John Ruskin. Lecture at Oxford. Nov. 1883. (Cook and Wedderburn ed. Vol. 33, p. 365.)

SIGNS are everywhere to-day that the desire is growing in us to put the house social more under considered control: we see that the happy-go-lucky individualism of the past must give way to a well-thought-out system, which will be to the greater good of a greater number; we see the need to infuse a greater share of human sympathy into commerce and industry, in place of the unbridled spirit of competition that has too long prevailed: in other words, there is an obvious desire to introduce scientific practice into our affairs, so that we may work with calculated effect.

Life is so complex that we have forgotten how entirely food is its foundation and mainstay. We have taken what is provided as a matter of course, with little thought for the stomach: too easily assuming that nothing unwholesome would be offered, scant allowance has been made for commercial greed. The use of crude fuels, such as coal and oil, has led us to overlook our own need of carefully chosen fuels of altogether special quality: in fact, twenty years ago, when the War began, we had but a few rough rules to guide us. The rapidly growing science of dietetics has been developed almost entirely since the War. We now know that Nature exerts her control by homœopathic means: that our gross foods are assimilated under the influence of indispensable very small proportions of a large number of accessory agents, in balance, each of which apparently serves the special ends of some one or other of the many separate, departmental activities of the human system. A trace of iodine may shift the balance from idiocy to sanity. No factory is in any way an approach to our bodies in complexity and perfection of organisation. Not a few of us look forward with comfortable assurance to a time when present-day curative medicine will give way to a preventive medicine which will all but insure health, through proper feeding. An Erewhonian situation will then prevail: disease will be punishable—because it will be admitted that it is mainly due to misfeeding and malnutrition.

Once established, this attitude towards health must affect our policy in every direction. In asking for a national stock-taking, Mr. Lloyd George has shown that he already has a dim notion of the coming state of affairs—when official ignorance will be overcome by constructive knowledge, broadly spread throughout the community, not localised in a bureaucratic service. We have to define an agricultural policy without further delay.

Milk will be our mainstay and primary care, being Nature's ideal food, the food of infancy. As a nation, we have yet to recognise the general value of milk; that the Milk Marketing Board should feel called upon to press it upon the attention of the medical profession, by a weekly advertisement in the *Lancet*, is not merely farcical but little short of a tragedy. We have to create a milk conscience in all concerned with its production. Proper conditions of cow-keeping must be enforced, throughout the country; we must not allow the trade to be in ignorant hands. If rigid count can be kept of publicans, control of dairymen should not be impossible. Maybe, if it

were taxed, as dear as beer, milk would be more valued and more popular. Everything has yet to be learnt about milk. Certain deficiencies are to be recognised even in the best product. Whether these are innate or the consequence of long continued malnutrition, due to exhaustion of our soils, is a question.

If cows came "from out the East", originally they will have been exposed to a fuller measure of sunlight than are our cows to-day; if so, their output of the much belauded D advitant may have been greater, particularly if better feeding put more ergot-sterol into the hides of the Eden herd. Eve, noticing that the animals generally ate it, may have been led to give a bite of grass or of some water weed to her infants with her milk; civilisation has made modern mothers less considerate, though I hear of my Californian great-grandson being given spinach from early infancy. In fact, we do not yet know what milk is, might be or should be. A vast field of scientifically directed, experimental inquiry lies open—real inquiry, not randomised re-search.

The inquiry into milk will involve no mere study of milk but also of the animals producing it and of the foods from which it is made. We may say already, that we know—some few of us feel it in our bones—that, like ourselves, when properly fed, cattle will be free from disease. Grass hitherto has scarcely been a cultivated crop—we have to study its cultivation, under the various conditions of soil and climate which prevail in our islands; this applies equally to other crops used in feeding farm animals. Milk will surely be found to vary in quality—eventually the districts producing it will be graded and specially named, as vineyards are in France and Germany: *Liebfraumilch* will not be the only brand: *Milch, Weib und Gesang* will be our modern *Sprichwort*. Our Wine and Food Society will have its milk tasters who will vie with Mr. André Simon as a wine taster; a Marcel Boulestin–Ambrose Heath combine will act as grass tasters to cow herds, as well as in testing our salads.

A problem to be inquired into is the cyclic variation with the year in grass and other green foods supplied to cattle. The plant must change its character in passing up to the climax of its growth and thence down to maturity. Milk must be correspondingly affected. At present, all that we know is, that some of the shortcomings in winter food may be met by rationing cattle with summer-grown grass, cut young and immediately dried with special care. In an experiment which I was instrumental in starting at Christ's Hospital, three winters ago, six cows out of a herd of thirty-six were fed with such grass, grown, cut and dried under the superintendence of Sir Frederick Keeble, at the Jealotts' Hill Farm of Imperial Chemical Industries, Ltd. Throughout the winter, the six remained sleek and gave a milk of summer character, whilst the rest of the herd fell off as usual, giving an ordinary poor winter milk. Similar results have since been obtained elsewhere. We may hope that, some day, winter conditions may be overcome by justifying the practice of the Laputan philosophers.

To produce grass of the right quality, the growing plant must be sprayed with water and even with fertilising solutions, at the expedient moment. The supply of water, therefore, must be taken into account and due provision made. Ultimately, it will be found that only certain districts are suitable for the production of a standard article—these will be definitely earmarked for the purpose and supply regulated to meet the demand.

In connexion with milk, butter and cheese will need special consideration—to what extent we are to supply ourselves with these. We are so ill-supplied now that the public is losing all sense of quality in cheese—the gullible housewife will take anything, provided it be in wedges wrapped in tin-foil, paying through the nose for it. Each county should have a cream cheese of note: dairymaids generally should be called upon to show that they have the imagination to produce distinctive articles: of what use are the bacteriologists if they cannot provide each county with its special cheese-bug, to be brandished against all comers from outside!

Our milk production should be strictly correlated with and regulate our output of meat—veal, beef and pork, even of poultry and eggs. Butter involves butter-milk and its use in pig and poultry keeping: not an ounce should be wasted. That Rothamsted should spend time and money in showing how it may be made harmless before turning it into a stream is nothing short of criminal condonation of manufacturers' ignorance. Verily is milk a dainty dish to set before king and nation!

Sugar may come next. We shall have to take this seriously, not as mere sweetness. In Europe it can only be produced at an economic loss; it has always been bounty fed. It may have agricultural advantages and suit our farmers under present conditions—but Peter is robbed to pay Paul, the community bears the brunt. Sugar can be made from sugar cane, at half the cost of

beet sugar, in the West Indies, Java, etc. We cannot but purchase some foreign goods in exchange for our manufactured goods—is not sugar one of the articles we should agree *to purchase*, on this account? There is no question of sweated labour to be considered: sunlight and the associated conditions in tropical countries all prevail against the economic cultivation of sugar here.

Maybe we shall soon be led to discourage the consumption of sugar and reduce its use to a minimum. Evidence is accumulating that it is an undesirable, if not a bad food, except when used to meet the strain of extreme muscular exertion, as in racing or climbing. The rise in the consumption of sugar, in modern times, is remarkable, especially in the United States; coincidently, there has been a marked fall in the amount of bread eaten. Americans are directing attention to a surprising change in national type—to the growth of obesity and even flabbiness in character. Are we not also losing character and becoming sugary in outlook? Sugar definitely spares fat—women are right in avoiding it, on this account. Worst of all, we starve ourselves in eating sugar in any quantity: it carries nothing with it—no mineral matter, nothing that is body-building. On this account it is bad for children. Finally, it is probable that resistance of infectious disease is lowered by an excess of sugar in the blood.

Follows bread. Society has a heavy indictment to bring against the medical profession in particular, in that it has so long allowed the use of white wheaten flour as bread—that it has not insisted on as much as possible of the whole grain being eaten. The faults of white flour are those of sugar—it is mainly of use as fuel and has little nutritive value. It is truly a whited sepulchre! Nearly the whole of the mineral matter and the vital components—the germ—are removed in the bran, which is not eaten but sold as offal, for use by animals; these get the best of the bargain. The use of such flour is traceable to American laziness, to the desire to avoid hard labour by the use of machinery, also the desire to do big business and supply the world—without counting the loss to American soil or European farmers. Wholemeal flour cannot be kept more than a few weeks, as the oil in the germ becomes rancid; white flour, being free from the germ, may be stored over long periods—it therefore suits the milling and baking trades. Canadian hard wheats have also an unfair advantage, in that the flour will carry more water: the baker can make more loaves from the sackful. Bread to-day is made *en bloc*—by machine: it is crustless and uninviting, as well as of minimum nutritive value. We need to go back to the local mill and the local baker—who together can give us a seemly loaf, of a bread containing as much of the cereal grain as may be eaten profitably. Maybe as good, if not better, breads may be made from home-grown than from imported wheats—putting aside all question of their water-carrying power.

Although Rothamsted has grown wheat on the same land, under like conditions, during more than ninety years, with great show of statistics, nothing has been learnt of the nutritive value of the grain. In any case, not a sack of flour should be allowed to come into the country—only grain, to be ground here. Our present fiscal policy will need drastic revision, if our knowledge of food be allowed to play any part in determining its character and scope. So will our agricultural research.

Last, but not least, "'tis but the means to do ill deeds that makes deeds ill done". This applies equally to the good deed of growing high quality crops: to water and manures, without which, in due season, nothing is possible. Agriculture has two great problems to consider—that of water-supply and that of waste-disposal. Neither can be discussed here. Suffice it to say, we cannot afford, any longer, *to waste organic matter*: we must have humus manures, if we are to put quality into agricultural produce, especially into table vegetables. All town waste must be collected and specially treated: Sir Albert Howard and others, working in India, have shown how this can be accomplished. Our people will perish, not from lack of knowledge but of organic manure, if this be not soon done. In addition, we cannot any longer allow sewage to go to sea: we must in some way recover from it both potash and phosphate, of which the natural stores are very limited. China calls to us, offering an example of thriftiness that we shall be compelled to follow. Our agricultural research stations fail us, not only in this particular but generally in matters of food production. They offer us only bare figures. Man unfortunately lives not by statistics.

A great renascence awaits us. We have to brush the pedant aside and make our universities of avail in the service of the nation. Education at the present day is worthless for all practical purposes; its fulcrum, in future, must be the belly through favour of the farmer.

HENRY E. ARMSTRONG.

Stability of Structures*

By J. S. Wilson

THE meaning of stability is not easy to define. In dynamics and mechanics we have stability of steady motion and stability of equilibrium, of position and of friction. To the civil engineer the word is usually applied to the power of a structure to withstand for an indefinite time all the loads and forces that may be brought to bear on it.

The most stable structure ever built is probably the Great Pyramid of Egypt. It consists of large blocks of limestone carefully shaped and piled together to the height of 480 ft. on a base measuring 830 ft. square. Another example of a great pile : a pile of bricks laid one on another, was a tall chimney such as the celebrated one at St. Rollox in Glasgow. This had a height of 435 ft., and at its base a diameter of 40 ft. It was pulled down a few years ago after having stood since 1842. A masonry dam built across a valley to impound water is a form of structure the stability of which must be beyond question, as failure would lead to disastrous flooding. Then we have the arch, the most beautiful and fascinating form of construction invented by man. In its simple form we have arches of imposing size and graceful stability across rivers, while in cathedrals and other great buildings we have it in the groin, dome and buttress.

In each of these examples, strength and stability depend mainly on the resistance to compression offered by stone or brick. A complementary form of structure, dependent on the resistance to rupture by the pulling asunder of its parts, is the suspension bridge, the stability of which depends almost entirely on the tensile resistance of the chains or cables. The greatest structure of this form is undoubtedly the George Washington Bridge over the Hudson River, New York, with its span of 3,400 ft.

In most iron and steel structures the resistance of the material to both tension and compression contributes to their stability in equal proportions, as is found in the great girder and cantilever bridges. Reinforced concrete, in which the great strength of concrete to resist compression is combined with the power of steel to resist tension, owes its development largely to the facility with which it can be built and shaped. Tunnels of masonry or brickwork, and cast-iron lined tube tunnels, subject to the pressure of great depths of earth, are forms of structure the stabilities of which are not easy to calculate.

* From the presidential address to Section G (Engineering) of the British Association delivered at Norwich on September 5.

There are two sides to all problems in stability; the first depends on applied mechanics, the second on the regulation of stresses to get an economical use of material. Progress in the second during the last fifty years has not been so great as in the first, to which my remarks refer more particularly. To fix the directions of, and arrange for the balance of, loads and forces, the conception of action along lines was introduced at an early stage. The position of such a line, with respect to the boundary of a member offering resistance, governs the distribution and intensity of stresses in the material. In estimating the intensity of stress, the position of the line in a lamina of the part under consideration is usually considered, and in it the distribution of the stress follows the 'trapezium law', which is a particular case of Galileo's solution of the beam problem. Thus if the line representing the centre of action of the load or thrust is on the centre of the section of the member, the stress intensity would be the same throughout the section. If the line of action is off the centre, then the intensity is increased on the side towards which the line has moved. The diagram representing the distribution of stress is a trapezium, the centre of gravity of which is on the line of action.

In a pier or buttress which supports and at the same time resists the thrust of an arch, the line representing the resultant of the weight and thrust of the arch is deflected downwards by the weight of the buttress, and the buttress may be so shaped that the deflected line is everywhere near the centre giving a uniform intensity of stress in the masonry, and uniform pressure on the ground below the foundations. On the other hand, the balance may not be so good, and the line may be towards the outer side of the buttress, giving high concentration in the masonry and ground.

Historically, the problem of the masonry arch is extremely interesting. The arch form of construction has been known for thousands of years, and several magnificent arches built by the Romans are still in a very good state. Real progress in the theory of the design and strength of the arch is comparatively recent.

In a masonry arch the line of thrust might occupy one of a variety of positions any of which would satisfy the requirements of equilibrium. For the purposes of design or estimating stability, some particular line must be chosen, and this can only be done by making assumptions, the validity

of which must have regard to the method of construction and the probable conditions of stress in the masonry. One assumption relates to the position of the line of thrust at the crown or springings. Since 1870, one of the advances made has been the introduction of definite hinges, at the crown or at the springing level, or at both places, to ensure the line of thrust passing through those points. These hinges render the problem of strength and stability much more definite, but with respect to arches without hinges the position is unchanged, although much has been done by comparing and analysing existing structures. In the monumental work by Séjourné[1], particulars are given of all arches of appreciable size throughout the world: details of construction are given, and the proportions are analysed and compared.

Up to the first half of the nineteenth century, knowledge of the strengths and characteristics of materials, and of the branch of engineering science now known as 'applied mechanics', was not sufficient to establish or disprove the accuracy of various theories relating to the design or stability of a masonry arch then in vogue or from time to time propounded; efforts to make progress in the problem depended almost as much on dialectics as on mechanical principles.

Throughout a long period in the eighteenth and nineteenth centuries, mathematicians and others applied themselves to finding the exact form of the line of thrust that would ensure equilibrium in a mass of masonry bridging a void. The upper boundary of the mass was a horizontal surface representing the road surface and the lower one the intrados of the arch, shaped to conform to the line sought.

The shape of this arch of equilibrium was compared in great detail with those of the ellipse, cycloid, parabola, catenery and semi-circle or segment of a circle. Different writers strongly advocated one or other of these curves as being the true curve for an arch. The elaboration with which this was done seems remarkable, for many must have known that to build an arch to conform to a particular curve with the exactitude suggested is practically impossible. When the centering on which an arch is built is removed and the arch supports itself, the compression of the mortar in the joints and of the voissoir stones allows the arch to drop an amount which is quite sufficient to alter the shape appreciably; thus the arches of Perronet's famous bridge at Neuilly dropped, on decentering, enough to alter the radius curvature at the crown from 150 ft. to 244 ft., and if intended to be elliptical, it might have conformed actually more closely to a cycloid.

For the longest spans, reinforced concrete has now superseded masonry; but fine masonry arches of 300-ft. span have been built. The construction of spans of increasing length has been made possible by improved technique in building. To avoid high stresses arising at the springing and key stone, as a result of the settlement or elastic deformation of the centering, as weight is added during building, and as a consequence of the initial deformation of the arch itself when the centering is removed, gaps are left in the arch, and special forms of construction are now introduced to act as temporary hinges, so that when the bridge is completed and the gaps filled in, the position of the line of thrust is fairly definitely known. In reinforced concrete arches, either permanent hinges of steel are introduced or else all the reinforcing bars are drawn together at the critical points to form a temporary hinge, and the surrounding concrete is filled in only on completion. Reinforced concrete arches with spans as great as 590 ft. have been constructed.

The stability of a masonry dam is a problem that has exercised the minds of engineers and mathematicians for many years. The failure of the Bouzey dam in France in 1895 gave prominence to the problem. The Bouzey dam was straight with a length of 1,720 ft., and the water held up had a maximum depth of about 40 ft. When the dam failed, the upper 30 or 35 ft. of its height for a length of 560 ft. was swept away, and the flood, passing down the valley, caused great havoc, and eighty-six people lost their lives.

Investigations after the disaster revealed many points of interest. In the original design, the maximum pressure on the masonry was the only factor considered in calculating its proportions. In the course of the investigations after the disaster it was shown that the resultant of the thrust combined with the weight of the masonry was so placed that a tensile stress of 1·3 tons per sq. ft. must have been imposed on the masonry. Laboratory tests proved that the maximum tensile strength of the masonry was only 60 per cent higher. In opposition to the theory that the parts that failed had overturned by virtue of this weakness, it was held by some that failure was by shearing; the shearing stress being calculated as 1·32 tons per sq. ft. by some, and as 3·2 tons per sq. ft. by others.

Rankine, in 1871, had recommended that no horizontal joint in a dam should be expected to withstand any tensile stress; in other words, there should be no uplifting tendency. After the Bouzey disaster it was considered advisable that at the upstream face there must always be a definite compressive stress, and the French Government introduced the regulation that on horizontal joints there should be a vertical compressive stress at the water face equal to not less than the water pressure at the

joint. Such compression in the masonry would tend to prevent access of water to any joint or crack.

The late Sir Benjamin Baker, in 1904–5, at the time when I was his chief assistant, was faced with the problem of raising the Assuan dam. (At present the dam is being raised a second time.) The investigations after the disaster in France had shaken confidence in the accepted method of gauging the stability of a dam, and in 1904 a memoir was published entitled "Some Disregarded Points in the Stability of Masonry Dams", by Prof. Karl Pearson and Mr. Atcherley. By mathematical investigation, the authors concluded that although a dam might satisfy the usual conditions regarding the stresses on horizontal planes, it might still be subjected to dangerous tensile stresses on vertical planes in the vicinity of the downstream toe. That conclusion seemed most unlikely to engineers interested in the subject, but however incredible it might seem, it demanded attention as coming from so eminent a mathematician. In arriving at their results, the authors of the memoir based their calculations on an assumed law governing the distribution of shearing stress across the base. The unsatisfactory state of affairs could only be cleared up by determining the distribution of sheer and other stresses.

Jointly with my friend the late William Gore, I made an attempt to do this, and we embarked on a series of elaborate experiments with india-rubber models.

Our investigations were described and discussed at the time at the Institution of Civil Engineers[2] and in *Engineering*[3], in which journal there was correspondence on the subject.

The models were made of slabs of rubber 1 in. thick with a smooth white surface, and shaped to represent the transverse section of a dam. The model was strained by weights carefully adjusted to represent the water pressure against the face and the weight of the masonry, on the assumption that the masonry had a specific gravity of 2·25. The model was divided into sections, and the 'masonry weights' were hung on transverse pins put through the rubber. Plates pulled by cords against the water face represented the water pressure. To ensure the exact relative positions of the loads, the model was so shaped that when fully strained it had the correct profile. A network of lines was ruled on the rubber, and large-sized photographs on plate-glass were taken under the strained and unstrained conditions. Corresponding lengths on the two negatives could be measured accurately, and from them the strains and stresses were calculated. The intensity of shear at various points was measured by comparing angles on the two plates. Our investigations enabled us to plot curves of stress-distribution on section lines at various heights. The curves were of quite definite shape. We found no evidence of the reputed tensile stress at the downstream toe. The shear stress diagram was practically a triangle with the maximum at the downstream edge, and the vertical stress distribution agreed substantially with the 'trapezium law'.

These experiments helped materially to clear up the situation and to re-establish confidence in the method that had been in general use for estimating the stability of masonry dams.

During the last few years, investigations of problems relating to the design of large concrete dams and curved dams have been made in the United States. The influence of heat, both natural and that generated by the setting of cement, on stresses and stability, has received much attention. In these gigantic structures, monolithic construction and the use of too large masses of concrete has been found accountable for serious cracking.

The suspension-bridge or 'philosopher's bridge', as it has been called, is a fascinating type of structure. In the course of the development of its design and stability there have been some astonishing occurrences. In its most elementary form, the suspension-bridge formed of strong flexible climbing stems or roots has been used by primitive peoples for centuries. Examples made of wrought iron appear to have been in existence in the eighteenth century. At the beginning of the nineteenth century the chains, which were made up with several links side by side, connected with common hinge pins, were of uniform strength throughout their length, and the road or platform was suspended by vertical rods. Within its limitations, this was a satisfactory form of construction. In a bridge which carries a series of loads on a flexible chain, the loads and the chains are only in equilibrium when the chain assumes an appropriate shape, and to support any additional weight or rearrangement of weights the chain changes its shape slightly. With a moving load, the tendency of the platform of a suspension-bridge to undulate with the passage of the load has handicapped the development of this type of bridge. An early attempt to use it for a railway proved a complete failure.

Telford's famous bridge across the Menai Straits, with a span of 570 ft., completed in 1826, is of the simple suspension type. At first the platform was too flexible and caused anxiety, but that part was altered and made stiffer. The bridge is still in service, and is standing proof that in principle and construction it was sound. A few years later, a supposed improvement, the 'taper chain' bridge, was introduced with the object of reducing the amount of iron required. The principle was unsound, and failures led to the suspension type of

bridge being regarded with suspicion for many years.

Several suspension-bridges, built before 1836, are still in use. In all these the chains are of uniform strength throughout, and the whole weight of the bridge is suspended from them.

The flexibility of these bridges under heavy moving loads is a source of trouble, and of wear and tear of the platforms. Nevertheless, when the chains are pulled by the loads into a line of equilibrium, so long as the anchorages are secure and the towers are sound, the stability depends solely on the tensile strength of the chain, and under these conditions almost all suspension-bridges have a substantial margin of strength or stability.

One of the early suspension-bridges still in use is that across the Thames at Marlow, built by W. Tierney Clark, in 1829. I examined and reported on this bridge some years ago and found it in a remarkably good state. In the development of the stability of suspension-bridges this one is of particular interest, for it was the first built with stiffening girders. The ends of the cross girders in this bridge are all stiffly connected by parapets made in the form of girders, and any cross girders on which a heavy load might rest cannot deflect the suspension chain, as it would do if the parapet girders were not there.

In the modern suspension-bridge the stiffening girder is as important a feature as the chain or cable, and its introduction has made it possible to construct the gigantic bridges in the United States. The interaction of the stiffness or flexibility of the girder with the curvature of the suspension cable is the governing factor in the stability of the modern suspension-bridge.

The latest example of suspension-bridge with its span of 3,400 ft. and others of more than 1,500 ft. compare with Telford's of 570 ft. and the others of 50–200 ft. Cables composed of thousands of steel wires, four times as strong as iron, laid side by side to form cables 3 ft. in diameter, take the place of the iron chains ; and the flexible timber platform, so easily deformed by moderate moving loads, is now replaced by deep steel stiffening girders with upper and lower decks providing double tracks for both electric railways and street trams and road width for many cars.

International Physiological Congress

MEETING IN THE U.S.S.R.

THE fifteenth International Physiological Congress met, under the presidential direction of Prof. I. P. Pavlov, in Leningrad and Moscow on August 8–18. The gathering proved of unusual interest, especially from the social point of view. The members, numbering more than eight hundred foreigners and about five hundred Russians, were given an opportunity to see something of the mechanism of the communistic regime. The several receptions and banquets in the old royal palaces gave the members a glimpse of the almost oriental splendour which surrounded the ruling class under the Czars.

The Russian National Committee and the Soviet Government treated the Congress with unique hospitality. From the initial, informal reception in the magnificent Marble Hall of the Ethnographical Museum in Leningrad, to the final banquet in the Grand Palace of the Kremlin, and the aviation display on the outskirts of Moscow, the entertainments arranged for the Congress were consistently lavish.

The three plenary sessions, at which five scientific papers were read by well-known physiologists, were the outstanding occasions of the Congress. The first plenary session was opened by Prof. Pavlov, who gave the Congress a stirring welcome. The paper delivered at this time by Prof. Walter B. Cannon (Boston) was entitled "Some Implications of the Evidence for Chemical Transmission of Nerve Impulses". It constituted an outline of present knowledge in the field of neurohumours. Both the sympathetic nervous system and its chemical representative, adrenalin, act in a widespread manner. Acetylcholine is the chemical representative of the parasympathetic nervous system. Unlike adrenalin, acetylcholine is very unstable. Thus its action is limited to the region in which it is produced. The action of the parasympathetic nervous system is similarly localised.

The evidence for the existence of two adrenalin-like or adrenergic neurohumours was cited. These were named sympathin E (excitatory) and sympathin I (inhibitory). Langley suggested this concept in 1905. He further believed that the differentiation probably takes place in the effector cells, and this is to-day unrefuted but unproved. Possibly the sympathetic mediator, acetylcholine, has excitatory and inhibitory forms. At present,

however, this substance has never been obtained in a specific form. The action is always either excitatory or inhibitory, depending on the function of the parasympathetic nervous system in the organ involved.

The evidence for the chemical mediation of autonomic nerve impulses at the periphery is convincing in the cases of non-striated and cardiac muscle, digestive and sweat glands. There is certainly suggestive evidence for a chemical mediator, acetylcholine, of motor nerve impulses to striated muscle. The recent work on non-striated and cardiac muscle, showing spatial and temporal summation of nerve impulses, gives strong support for the theory of the quantal production of chemical mediator by each nerve impulse.

The evidence for chemical mediation between neurones is quite convincing in the case of sympathetic ganglia. Synaptic transmission in the central nervous system may be by neurohumours although the evidence for this is meagre as yet. Prof. Cannon ended by commenting on the fact that progress in this field is so rapid that his treatment of the subject was probably not strictly up-to-date.

The secondary plenary session opened with a paper by Prof. L. A. Orbeli (Leningrad) on "Pain and its Physiological Effects". A detailed account of the work of the British neurologist, Henry Head, on the problems of pain was given. Much of Head's work, performed in 1905, has been repeated and verified quite recently in the Soviet laboratories. Orbeli believes that he has shown that sympathetic nerve distribution is regional. Thus one nerve cell branches to give fibres to skin, muscles and internal organs of a given cross-section of the body. He believes that 'referred pain' operates through this sympathetic mechanism.

When a visceral organ is diseased, sympathetic impulses are set up which, travelling to the skin, alter the degree of excitability of the sensory endings there, giving hyperæsthesia or pain.

Sir Joseph Barcroft (Cambridge) presented, also at the second plenary session, a paper on "The Velocities of some Physiological Processes". Dealing chiefly with respiratory mechanisms, he pointed out the necessity of comparing the velocities of the chemical and the physical processes involved. In the ordinary loading and unloading of oxygen the chemical events take place so much more rapidly than the physical that only the rates of the latter need be considered. However, the chemical velocities assume special importance in some cases. Hæmoglobin takes several hundred times as long to part with carbon monoxide as with oxygen. This fact is of prime importance in the study of carbon monoxide poisoning.

Chemical velocities in respiration become specially important in muscles which act rhythmically over long periods of time. In these places oxygen transport from capillaries to tissue cells is accomplished by muscle hæmoglobin (myoglobin), and in some species by cytochrome. Myoglobin is six times as fast as hæmoglobin in its reactions with oxygen. Cytochrome is even faster. This velocity assumes real importance in certain cases, as in the hearts of small mammals and birds, where the heart rate may approach one thousand beats a minute.

The velocities of intracellular oxidations and the catalysts involved were discussed at some length. One molecule of oxygenase, probably the chief intracellular oxidative enzyme, can deal with one hundred thousand molecules of oxygen per second at 10° C. If the molecules are dealt with one after another, the interval between molecules will not be more than ten millionths of a second. Assuming an adequate concentration of the enzyme, this velocity would not constitute a limiting factor for even the fastest physiological process.

The velocity of the chemical process involved in the dissipation of carbon dioxide in the lungs is very slow. Between the breaking up of sodium bicarbonate in the body and the evolution of carbon dioxide there is the slow formation of carbon dioxide and water from unionised carbonic acid. Recently it has been shown that the latter process is speeded up by an enzyme, carbonic anhydrase, which is found in the red blood corpuscles. The bicarbonate obtains access to the enzyme through exchange with the chloride ions inside the corpuscles.

Sir Joseph Barcroft ended by pointing out an interesting discovery resulting from the study of chemical velocities. Consideration of the rate of evolution of carbon dioxide has led the Cambridge group of workers to the conclusion that 2–10 per cent of the carbon dioxide in the blood is present, not as bicarbonate, but in the more active carbamino form.

Prof. L. Lapicque (Paris) delivered the first paper of the third plenary session, held in Moscow, on "Some Recent Advances in the Knowledge of the Nervous Mechanism". The well-known concepts of chronaxie, isochronism and heterochronism were treated. New experimental material was brought forward in support of the speaker's disputed views on these subjects. Lapicque and his colleagues have found that muscles which work together have the same chronaxie ; antagonistic groups have different chronaxies. He also finds changes in the chronaxie of peripheral nerves following central nervous activity. Indeed, when a conditioned reflex is elicited it is claimed that the peripheral portions of the pathway undergo a change in chronaxie due to the central activity.

The final paper of the third plenary session was given by Prof. A. A. Ukhtomsky (Leningrad) on "Physiological Lability and the Act of Inhibition". An account was given of the research work conducted in the Russian laboratories in an attempt to show the relation between chronaxie and what they term "functional lability". This "functional lability" is defined as the factor limiting the conduction of impulses in any excitable tissue. It determines whether a tissue is excited or inhibited by a stimulating agent. Both processes, they intimate, are active, and both must be initiated by stimulation.

The general meetings were divided into thirty sections according to subject, five sections usually operating at one time. At these meetings, 485 papers were presented. In the appended table the papers are grouped under twelve subject headings. This table gives some indication of the interests of physiologists in the countries represented at the Congress. The body of material presented was so large and varied, and the time so short, that many members found it difficult to glean much of value from these meetings. An attempt will probably be made, at the next Congress, to rectify this weakness in the programme arrangements.

CLASSIFICATION OF PAPERS PRESENTED TO "THE 15TH INTERNATIONAL PHYSIOLOGICAL CONGRESS"

Subject	Number of Papers Presented From U.S.S.R.	From other Countries
Applied Physiology (industrial)	8	4
Biochemistry	20	69
Circulation and Heart	4	19
Excretion	2	9
General and Cellular Physiology	24	51
Internal Secretion	8	25
Metabolism, Nutrition and Vitamins	4	28
Nervous System and Nerve-Muscle Physiology	65	59
Pharmacology	15	19
Physical Factors in Biology	5	8
Sense Organs	11	13
Sexual Cycle	4	11
Totals	170	315
Total Number of Papers	485	

The U.S.S.R. research centres provided a notable group of permanent demonstrations. In part, these served to show the type of experimental work in progress. The Soviet physiologists are chiefly occupied in researches on the nervous system with special reference to conditioned reflexes, researches in the industrial aspects of work, and researches into the special physiology of the woman and the child. The table summarising the types of papers presented at the general meetings gives further indication of the trend of physiological investigation in the U.S.S.R.

To a large extent, the aim of the permanent demonstrations was to show the expansion of scientific laboratories and personnel under the Soviet regime. This aspect was further stressed when the delegates were taken to visit the various laboratories. The expansion has been amazing. In the days before the revolution there were 24 institutions carrying on physiological research. To-day there are said to be 380 such institutions. The increase in personnel has been correspondingly great. Scientific people cannot but applaud the attitude of a State which so generously supports scientific endeavour. One wonders, however, if such expansion can be altogether sound. The All-Union Institute of Experimental Medicine (VIEM) had a staff of 393 in 1931 which has been increased to 2,200 for 1935 ; the increase in monetary grant has been commensurate. Expansion of this nature is to be found on all sides in the biological and medical sciences. It is a rate of expansion which would hopelessly overtax the highly developed educational facilities of either Great Britain or the United States of America. Just how well the less extensive Soviet educational system equips its scientific workers is a matter for conjecture. It is certain that the body of Soviet scientists know too little about what is going on outside the U.S.S.R. Practically none of them has studied abroad. Foreign scientific journals are scarce. Although the U.S.A. and the U.S.S.R. are comparable countries from the point of view of numbers of workers in biochemistry and physiology, the *Biochemical Journal* has 346 subscribers in the U.S.A. and only 46 in the U.S.S.R., the *Journal of Physiology* has 211 subscribers in the U.S.A. and only 26 in the U.S.S.R. The scarcity of periodicals in foreign languages other than English is apparently even more serious.

There is certainly no lack of interest in the work and opinions of foreign scientists. A well-known English monograph on a physiological subject was recently translated into Russian and printed by the Soviet authorities. Three thousand copies were sold in about a month, a remarkable sale for a scientific monograph in any language. The young Soviet scientist is enthusiastic and eager for knowledge. It is to be hoped that the international attitude shown by the Soviet Government in its treatment of, and its speeches to, the Congress will be extended to the training of its own scientists.

One of the most important features of the Congress was the report of the Permanent International Committee, delivered to the third plenary session in Moscow by its secretary, Prof. A. V. Hill. The Committee regretted the retirement of W. H. Howell (Baltimore) and J. E. Johansson (Stockholm). W. B. Cannon (Boston) and G. Liljestrand (Stockholm) were elected in their places. The other members are F. Bottazzi (Naples), O. Frank (Munich), A. V. Hill (London), L. Lapicque (Paris) and I. P. Pavlov (Leningrad).

The 1938 Congress was invited, by Prof. Hess and the Society of Swiss Physiologists, to meet in Zurich. This invitation, on the recommendation

wide and detailed knowledge of social institutions, customs and beliefs, enriched by the information collected in an ethnographical survey, which he conducted in 1902–9, appeared to advantage in his "Castes and Tribes of Southern India" (1909), in which he added to his own observations a digest of a vast amount of other material. No less remarkable in the character of its observations and its originality was "Omens and Superstitions of Southern India", a book which has proved of the greatest interest and value to students of folklore and religion.

Thurston was ever generous in placing his material at the disposal of others. Not only were his researches of the greatest utility to Sir Herbert Risley in his ethnographic survey work in India, but also it was largely owing to Thurston's assistance, which extended from the organisation of transport to counsel and information in matters of ethnographic detail, that the late Dr. W. H. R. Rivers owed, as he himself acknowledged, the remarkable achievement of his anthropological investigations among the Todas of the Nilgiri Hills. Thurston's retirement was a loss to anthropological studies in the Madras Presidency, of which the effect is still apparent. No one has quite taken his place.

We regret to announce the following deaths:

Prof. G. Buchböck, professor of chemistry in the University of Budapest, aged sixty-six years.

Dr. H. W. Dudley, O.B.E., F.R.S., of the National Institute for Medical Research, known for his work in biochemistry, on October 3, aged forty-seven years.

Prof. Rhoda Erdmann, director of the Institute for Experimental Cytology in the University of Berlin, and editor of the *Archiv für Experimentelle Zellforschung*, on August 23, aged sixty-four years.

Mr. G. H. Hamilton, official astronomer in the Jamaica branch of the Harvard Observatory in 1922–24, and since 1924 astronomer of the Hamilton Observatory, Mandeville, Jamaica, on August 6, aged fifty-one years.

Mr. W. K. Laurie-Dickson, who was associated with Mr. Edison in studies of the Edison effect, and for many years superintendent of the Edison Electrical Works, on September 28, aged seventy-five years.

Major R. F. Stirling, director of veterinary services, Central Provinces, India, known for his work on animal diseases, especially rinderpest, on August 16, aged forty-eight years.

News and Views

Safeguarding of Peace

"Collective Security" is a problem which to-day is thrust upon the notice of every newspaper reader. Few of them are aware that to the scientific investigation of this same problem in international relations two whole years have just been devoted by a score of national groups and institutions affiliated to the Permanent International Studies Conference. At the London session of the Conference, held last June, the investigations culminated in a discussion directed more particularly to four essential aspects of the subject: the notion of collective security, the prevention of war, determination of the aggressor and sanctions, and the question of neutrality. The major portion of the deliberations was devoted to the principle of the organisation of pacific systems destined to eliminate the causes of war to the fullest possible extent. In connexion with the repression of war, the discussion turned on regional agreements and the relative value of various forms of sanctions, notably economic and military. There followed an examination of the notion of neutrality and the different forms it may assume when the collective machinery set up for the safeguarding of peace has to be put into operation. The subject chosen for the next Study Conference to be held in 1937 is 'Peaceful Change', with special reference to questions of (*a*) population, migration and colonisation, and (*b*) markets and the distribution of raw materials. The proceedings of the London session are summarised in Appendix 6 to the Report of the International Committee on Intellectual Co-operation (League of Nations Publications, 1935, **12**, *A* 2. Allen and Unwin, 2*s*. 6*d*). The same report outlines definite proposals submitted by M. Jean Gérard, secretary-general of the International Union of Pure and Applied Chemistry, for establishing closer collaboration between the International Committee on Intellectual Co-operation and the International Council of Scientific Unions. The proposals are to be laid before a special committee of this Council, appointed to deal with the subject.

New Commission of the R.R.S. *Discovery II*

The Royal Research Ship *Discovery II* left London on October 3 on her fourth Antarctic commission. The voyage is expected to last for some twenty months, and, as on former occasions, the work is primarily concerned with observations on the distribution and environment of the whales which form the basis of the southern whaling industry. According to the programme which has been arranged, the ship, after calling at Cape Town, will circumnavigate the Antarctic continent, returning to South Africa in June 1936. The distribution of whales near the ice edge will be examined in each sector of the Antarctic, and series of stations with full observations on the hydrology and plankton will be taken on lines extending from the pack ice to the warmer waters north of the Antarctic convergence. This circumnavigation is being made in the summer months, and will be complementary to that undertaken in the winter of 1932. The work is controlled by the *Discovery* Committee

acting under the instructions of the Secretary of State for the Colonies. The present voyage is under the leadership of Mr. G. E. R. Deacon, with Lieut. L. C. Hill, R.N.R., in executive command. The other members of the scientific staff are Mr. J. W. S. Marr and Dr. F. D. Ommanney, with Mr. A. Saunders as laboratory assistant and photographer.

Racial Studies

A NEW publication devoted to racial studies may count with certainty on an interested audience at the present moment, when racial questions have come to have an outstanding importance in international and national affairs. Racial characters have ceased to be regarded as of purely academic interest; but since they have been made the pivotal factor in nationalist propaganda, the public, bewildered by conflicting statements as to the meaning and province of 'race' in the modern world, welcomes an impartial and scientific examination of both general and specific problems. The *Zeitschrift für Rassenkund und ihre Nachbargebiete*, which has completed its first volume by the issue of a third part in May last, has been founded for the purpose of examining problems of race on scientific lines, dealing not only with broader issues, but also investigating racial problems as they arise in defined areas and specific groups. The treatment of the subject is not confined to discussion of physical characters alone, but will take into account the evidence of psychology and social anthropology, prehistory and linguistics. It is proposed thus to cover the whole field of the racial problems which arise in the study of the development of man in time and space. The editor is Egon, Freiherr von Eickstedt, director of the Anthropological and Ethnological Institute of Breslau; and he has secured a promise of co-operation and collaboration from a large and representative body of anthropologists from all over the world. Two volumes of three parts each will be published annually at a subscription price of 22 gold marks for each volume. The first part of the second volume appeared in July.

Food of Peking Man

AN interesting light is thrown on the mode of life of Peking man in a communication by Dr. Ralph W. Chaney, of the Department of Palæontology, University of California, and research associate of the Carnegie Institution of Washington, D.C., which is issued in the *News Service Bulletin* of the Institution. It would appear that Peking man supplemented the meat diet provided by the game animals of the hills and plains by vegetable food, which he obtained as a 'food-gatherer'. About twenty feet above the lowest level of human occupation in the Chou-kou-tien cave and in a breccia containing numerous quartz artefacts and bone fragments, there is a layer several inches thick, made up of thousands of fragments of the shells of seeds. The markings on the shells indicate that they are hackberry seeds, globular bodies smaller than peas. The modern hackberry (*Celtis*) occurs as a small tree in the forests both of North America and Asia, but is most characteristic as a shrub on semi-arid slopes and stream borders. As it is improbable that they could have been introduced into the cave by any other agency than animals or man, it may safely be assumed that they formed part of the food of one or the other, their shells having been crushed while being eaten. In the United States the berries are extensively used as food by birds, rodents and the Indians, especially in the south-west. The most common use is as a flavouring for meat or bread. In order to eliminate the possibility of these seeds having been introduced into the cave by rodents, experimental observations have been made in which it was found that monkeys alone broke up the shells in a manner corresponding to that in which the shells in the cave had been broken. It is, therefore, more than probable that the seeds were brought to the cave by human agency and that the hackberry seeds afford the earliest known example of a vegetable food used by primitive man.

New Flying Boats for British Empire Air Lines

IT is announced that Imperial Airways have placed an order with Messrs. Short Bros., Ltd., of Rochester, for a fleet of flying boats specified to be both larger and faster than any of a similar class now in existence. The order provides several innovations, the most startling of which is that the type of engine will not be decided until absolutely necessary for the completion of the design. It will thus be possible to take advantage of accumulating experience in the use of several different types, some of which are as yet not very thoroughly tried out under such conditions. It is also understood that the number of machines to be ordered is not yet settled, but will depend upon their suitability for the varying conditions in the different Empire routes. The new boats are to be high-wing monoplanes, without external bracing, and carrying wing tip floats. These will be the first marine aircraft in Imperial Airways fleet to depart from the more usual biplane construction. The size of the hull is such that the forepart can be given two decks, the upper one for the crew, ship's offices, and cargo, and the lower one for passengers. Their total loaded weight will be 17½ tons, about 30 per cent increase upon the present largest boat in Imperial Airways service, of which 3½–5 tons is available for paying load, depending upon the length of the flight between refuellings. The estimated speed is nearly 200 miles per hour, with a range of up to 1,500 miles. This allows them to undertake the two longest stages of the all-Empire route (except the Atlantic), that between England and Gibraltar, and Australia New Zealand.

History of Medicine Congress at Madrid

AT the International Congress of the History of Medicine, held at Madrid on September 23 under the patronage of the President of the Spanish Republic, there was an exhibition of medical manuscripts, documents, instruments, etc. The Wellcome Historical Medical Museum contributed some

lustrations and objects to this exhibition. Among ıese were illustrations of Arabian surgical instruments ·om early fourteenth century manuscripts ; examples f the medical and other works of Maimonides, the lispano-Jewish philosopher and physician of the welfth century ; replicas of the earliest MSS. of the fe of Andres Laguna, physician to Charles V and 'ope Julian III ; Roman, medieval, Hindu and ıodern surgical instruments ; historical objects uch as Egyptian artificial eyes, anatomical models, nd a special section devoted to the evolution of spectacles. Part of the Museum's exhibit comprised interesting dioramas including Nicholas Monardes of Seville (1512–88) depicted working in his private museum of curiosities ; a historic incident connected with the discovery of cinchona bark as a remedy for malaria (1630) ; a thirteenth century apothecary's shop in Cordova (Fig. 1) ; and an interior view of the hospital of Santa Cruz at Toledo as it appeared in the sixteenth century.

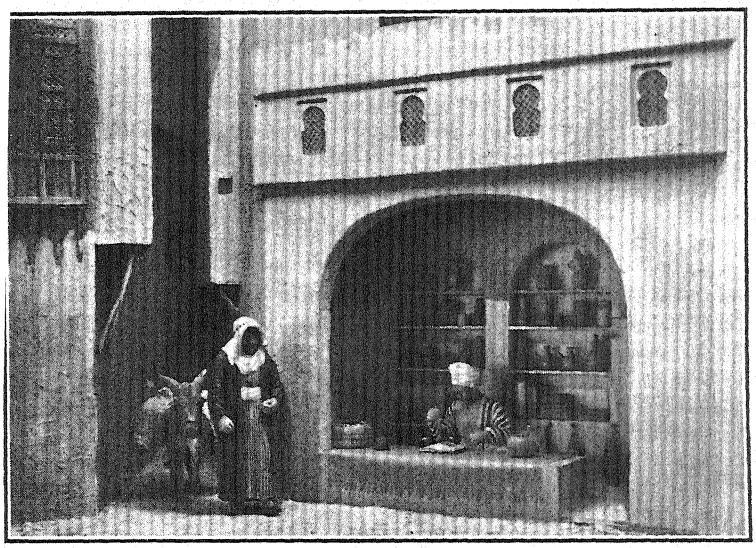

FIG. 1. Diorama of a Hispano-Moresque apothecary's shop.

Scientific Control of Road Traffic

ON September 10, at the British Association meeting in Norwich, Mr. A. T. V. Robinson opened a joint discussion in Sections G (Engineering) and J (Psychology) on the control of road traffic. He said that the question is far wider than merely the prevention of accidents ; that it is how to move with a minimum of delay, discomfort and damage a system consisting of heterogeneous units of passengers and goods travelling for industry and pleasure in all directions. Of the year's total of 7,000 fatal accidents, about 2 per cent were due to the defects of the vehicle, somewhat less than 2 per cent to defects of the road, and the remaining 96 per cent were due to the personal equation. Engineers study either the roads or the vehicles, and the psychologist studies the drivers and pedestrians. Mr. Robinson emphasised the importance of the colourisation of the 'carpeting' of the road, and said we ought to endeavour to get road carpeting of a lighter hue. In the future it is possible that on all the busy roads lights on the vehicles may be unnecessary and the approaching driver will see the oncoming vehicle, not as a couple of spots of dazzling light on a black background, but as a dark silhouette against an adequately illuminated road. The improvements in vehicles, especially the introduction of four-wheeled brakes, has greatly facilitated free movement of traffic on the streets, and the compulsory test for every new driver has worked admirably, about 12 per cent being rejected. It is recognised that certain drivers are 'accident prone', and these must be eliminated as soon as possible. Science may help us to keep the demonstrably unfit off the road, but until science, and not a human driver, assumes control of the vehicle, occasional breakdowns in traffic control are bound to occur.

Fewer Accidents in Well-Lighted Streets

ACCORDING to the *Electrician* of September 20 the first accident statistics for the section of the highway between Versailles and Ville d'Avray have been published. This road has recently been lighted with sodium vapour lamps (discharge tube lamps), and the statistics show a reduction of 74 per cent in the number of accidents, none of which was of a serious nature. Local authorities should consider these figures, which prove that lives can be saved by the proper lighting of rural roads.

Closing Down of Private Electric Generating Stations

SEVERAL of the large factories in Great Britain have been considering whether it is an economical proposition to close down their generating stations and take their electric supply from the Grid. As the facilities offered by the public supply increase and the price diminishes, the advantages in its favour are rapidly increasing. Messrs. Lever Bros., of Port Sunlight, who were well known to have one of the largest and most efficient private plants in the country, have now entered into an arrangement whereby their power station becomes associated with the Grid, and will, under the direction of the Central Board, be operated by the Birkenhead Station. The load taken will be 40 million units a year, which is equivalent to the needs of a large town. The consumption of Birkenhead itself is 41 million units and the consumption of towns such as Oxford, Peterborough and Plymouth are less than 40 million units. Port Sunlight, the centre of the great soap and similar products manufacturing business, has an area of about 2,000 acres, and several other firms have established factories on the estate. The demand is likely to increase in the future. Among other large firms which have recently changed over from a private to

a public supply are the steelworks of Stewarts and Lloyds at Corby, those of Firth Brown at Sheffield and the thread mills of J. and P. Coats at Paisley.

High-Definition Television Transmission

IN connexion with the high-definition television transmissions which will be radiated from the Alexandra Palace, the British Broadcasting Corporation has requested Baird Television, Ltd., and Marconi-E.M.I. Television Co., Ltd., to send to manufacturers a complete specification of the wave-form which they will radiate in their television transmissions from the palace. We have received from each of the companies their specifications, which are highly technical and will be mainly of interest to manufacturers. The ratio of the horizontal to the vertical breadth of the pictures is four to three for the Baird transmissions and five to four for the E.M.I. transmissions. The latter system transmits 25 complete pictures per second each of 405 total lines. These lines are 'interlaced' so that the frame and flicker frequency is 50 per second. It is claimed that good pictures can be received, although only a fraction of the radiated band is used; but the greater the width of the transmitted band utilised the better the received picture.

High Pressure Turbine Practice

IMPORTANT developments are taking place in the large power stations of electric supply companies. In the *Electrical Times* of September 19 there is an interesting account of the Loëffler boilers, which will supply steam turbines at the enormous pressure of 2,000 pounds per square inch. The exhaust steam from the high-pressure turbine is at a pressure of about 195 pounds per sq. in. and is reheated by steam from the boilers before passing into the low-pressure turbine. The North Metropolitan Supply Co. has two stations at Brimsdown called *A* and *B*. In the old station *A* the conditions were unfavourable to economical generation as the turbine pressure was only 150 lb. per sq. in. Owing to the favourable economic possibilities offered by the Loëffler boiler the station is being altered; two boilers each having a capacity of 210,000 lb. per hour, each operating at a pressure of 2,000 lb. per sq. in. and at a total temperature of 940° F., have been ordered from the Mitchell Engineering Co., Ltd., which has acquired the British rights from the well-known firm of Vitcovice. If petrol drops on the steam pipes at these high temperatures it bursts into flame. About twenty of these boilers are used abroad in Czecho-slovakia, Germany and Russia. To get the best results it was necessary to have a set of 50,000 kilowatts. As a machine of this size could not be fitted into Brimsdown *A* it was divided into two. The high-pressure part has a power of 20,000 kw. and the low-pressure part has a power of 30,000 kw. It is claimed that certain advantages will accrue from running the machines in series.

The Lower Yield Point of Stress

THE report of the British Association (Section G), Committee on Stresses in Overstrained Materials, presented at Norwich, states that particular consideration has been given to the requirements of the engineering profession and industry in view of present and future developments. By the increasing use of electric and other methods of welding in structural work, the problem of plastic overstrain has reached such high importance as to become one of the determining factors in design, and the Committee puts forward the considered view that the so-called 'lower yield point' affords the most satisfactory and reliable basis for the comparison of structural steels. The several advantages attached to its adoption are set forth seriatim, and a draft specification is submitted. The Committee, of which the chairman is Sir Henry Fowler, expresses the opinion that the lower yield point should be included in the British Standard Specifications, and recommends that the desirability of its addition be brought to the notice of the British Standards Institution.

Publication of Scientific Literature

THE projects for scientific publication and bibliography (cf. NATURE, **133**, 641; 1934) have been implemented by a grant of 15,000 dollars from Chemical Foundation. As a result, a new Documentation Division of Science Service has been initiated in furtherance of activities in this field which were considered at a conference called by Science Service on July 11 and July 29. The immediate objectives being attempted under the grant are the development of camera, projection pointer, reading machine for microphotographs and other means for photographic reproduction, and the establishment of a project for the photographic publication of papers which at present cannot be published promptly or in full. This undertaking will be carried out with the co-operation of existing scientific journals and societies. The plans of the new division are outlined in a paper read by Mr. Watson Davis, director of Science Service, before the thirteenth Conference of the Institut International de Documentation at Copenhagen, September 9–14. It is considered that the scheme for the publication of scientific papers by microphotographic or similar methods should be self-supporting from the start. Possibilities of increasing the availability of existing literature by such methods are to be explored and the broad problem of scientific bibliography is also to be studied.

San Diego Natural History

SEVERAL papers recording new work have been published recently in the *Transactions of the San Diego Society of Natural History*. Vol. 8 (Nos. 6, 7, 8, 9), March 1935, contains a paper on new marine mollusca of West Mexico by Herbert N. Lowe, a description of a new trilobite from Northern California by Harry E. Wheeler, a revision of some Californian *Astrodapsis* by George L. Richards and some new species of molluscs of the genus *Triphora* by Fred Baker and V. D. P. Spicer. Both the mollusc papers deal with the shells alone, but there is in the first a good annotated list of shells collected at Punta Penasco, Sonora, Mexico. The trilobites include a very well preserved specimen

f a new *Griffithides* from the Permian Nosoni formtion, its nearest known relative being *G. acanthiceps* om the Carboniferous limestone of England. A econd paper by the same author discusses and reescribes the original type specimen of Vogdes' *hillipsia* (*Griffithides*) *ornatus* from the Lower Coal easures, Conway County, Arkansas, renaming it *riffithides conwayensis*.

Bird Sanctuaries in London

THE industry of the voluntary observers who eport to the Committee on Bird Sanctuaries in the Royal Parks (England) gives a wonderfully full icture of bird-life in Greater London (Report of Committee for 1934. London: H.M. Stationery Office. 6*d*. net.). In Richmond Park, 56 species ored, and 38 other species were seen or heard; in Bushey and Hampton Court Parks, 52 species nested, including kingfisher and nightingale, and 26 others were seen. But the surprising thing is that, in the midst of the commotion of London itself—in Hyde Park and Kensington Gardens—there should appear visitors like the red-throated diver, the Slavonian grebe, and the golden-eye duck, all of them recorded for the first time in that area. It is said also that the Scandinavian form of the lesser black-backed gull appeared on the Serpentine in the autumn of 1933. Curious diversity in choice of roosting sites is shown by starlings and wood-pigeons: every evening about sunset, during autumn and winter, the latter leave St. James's Park, where there are plenty of suitable roosts, to spend the night in Battersea Park; and they make use of the very trees which some of the 2,000 starlings have sampled and abandoned before they continue their journey to roost in St. James's Park, which the pigeons have just left.

Research in the Tortugas Laboratory

THE section in the Year Book, No. 33 (1934) of the Carnegie Institution of Washington dealing with this station reports a number of workers during the season and a great variety of subjects. Although much work is done in the field, there is a notable increase from year to year in the use of apparatus requiring electric current. This will pobably necessitate the installation of a power plant of greater capacity in the future. Dr. Alan Boyden, continuing his serological studies of invertebrates, has used examples from many different phyla, including 7 molluscs, 4 arthropods, 8 echinoderms and 5 chordates. The results have been very satisfactory, and will enable light to be shed upon some of the more obscure relationships between the major groups of animals. Other researches include a study of the ecology and physiology of corals by Prof. C. M. Yonge, who found that the opportunity to examine the reefs in detail was of special value in view of his previous experience with Pacific coral reefs, and Mr. J. E. Harris's observations on the swimming movements of fishes, which embrace work on the fishes in their natural surroundings besides cinematographic experiments with special relation to their fins, whilst Prof. W. H. Longley's subject is the systematics of the Tortugas fishes.

Marine Research at Cullercoats

THE Report for the year ending July 31, 1934, of the Dove Marine Laboratory, Cullercoats, Northumberland (Armstrong College), published by the Marine Laboratory Committee and drawn up by the director, Prof. A. D. Hobson, shows it was a period of expansion of the activities of the Laboratory. The research work of the staff has been well maintained and there has been an increase in the number of outside workers. A number of alterations have been made in the building, including the conversion of a little-used lecture room into a new laboratory in which about a dozen students can be accommodated, or five research workers. This can be used for experimental and chemical work for which the main laboratory is not suitable. The work on herring has been continued as agreed with the Ministry of Agriculture and Fisheries, samples from the catches from the local shoals landed at North Shields during the season of 1933 being duly examined. Further investigations on the shoals from other parts of the coast have been continued. In Dr. Bull's work on conditioned responses in fishes, special attention is being paid to temperature, and it is found that teleostean fishes generally are extremely sensitive to temperature and that they can react to it purposively. Experiments on the perception of changes in salinity are now progressing satisfactorily. An excellent paper on the British Sphæromatidæ (Crustacea Isopoda) by Joseph Omer-Cooper and J. Hedley Rawson is included in this report. One of the species (*Limnoria lignorum*) is of economic importance as it is a wood-boring form and very widely distributed. A detailed discussion on the distribution of the Sphæromatidæ is included. In his aquarium observations Dr. Bull makes some important observations on the enemies of the common star-fish *Asterias rubens*, and shows that it is the only food eaten readily by the sun-stars *Solaster papposus* and *S. endica* and the northern stone-crab *Lithodes maia*. Adult specimens of all three can be maintained in captivity for long periods on such a diet.

British Association Mathematical Tables

PROGRESS in the publication of these tables has been rather slower than was anticipated, chiefly owing to the great labour required in correcting the proofs. Vol. 5, containing the prime factors of all numbers up to 100,000, has now been passed for printing. Tables for cyclotomy and trinomial congruences, offered by Prof. L. E. Dickson, have been accepted for publication. With regard to Bessel functions, at least three volumes will be required. The first of these (forming vol. 6 of the Tables) is now in the press, and will be published shortly. The calculations for the other volumes will absorb the greater part of the Committee's time and money during the next year.

German Chemical Industry

SHORT summaries of papers delivered at the conference of the Deutsche Gesellschaft für Chemisches

Supplement to "NATURE"

No. 3441 SATURDAY, OCTOBER 12, 1935 Vol. 136

An Interpretation of Social Institutions

The Primordial Ocean: an Introductory Contribution to Social Psychology
By Dr. W. J. Perry. Pp. xi+380. (London: Methuen and Co., Ltd., 1935.) 15*s*. net.

DR. PERRY has made a study of some of the general principles underlying the development of human society, as he regards the most pressing need of the moment to be not the accumulation of facts, but the gaining of insight into their meaning and relationships. Every man is born as a member of a community, and cannot be considered apart from his social surroundings; by virtue of his 'innate' equipment or 'biological inheritance' he reacts in certain ways to his surroundings, but he has also a 'social inheritance'.

The initial function of intelligence in the formation of society must have been closely bound up with the innate side of behaviour. Once this has been accounted for it is possible to proceed to study man's institutional behaviour and the reactions of individual qualities and behaviour to these. Dr. Perry's first inquiry is what social activities are common to the whole of mankind and what are due to special circumstances. To elucidate the first problem, he studies the food-gatherers, as representing the most primitive conditions available to us, but even among these "there are practically no social institutions", and those they have adopted from the food-producers. Many characteristics that the food-gatherers may possess in common do not depend on ethnic affinities or environment, but appear to be common to mankind.

Early food-producing was largely organised round agriculture and the domestication of animals, but accurate information is lacking how these two industries came about. Although various simple traits were carried over from the earlier condition, it was agriculture, and to a less extent the keeping of domestic animals, that led to more or less stationary groups and to living in stable communities. Hence arose the complications due to social relationships and to ritual and ceremonial observances and out of these developed religion as organised by priests. The high priests of the State cults became kings, and the royal families strove to control the whole organisation of the States. Food-production has enabled mankind to multiply enormously and has involved man in all sorts of new activities. Many social institutions have been based upon it, or greatly influenced by it. The organisation of the State, the functions of the kingship, religious ceremonial, magic, all these, according to Dr. Perry, have become associated with the great food quest.

A social institution comes into being for some definite reason: it persists for reasons that may be very different, and then a process of action and interaction is set up between it and other social institutions—human sacrifice and the wearing of clothes are examples. Painting, dancing, the drama, games, all appear to us to be 'natural', to spring immediately from innate tendencies. But the study of these activities shows that this conjecture is false. They came into play for some definite purpose, though afterwards they were practised for their own sakes.

The accumulation of possessions is not a characteristic of food-gatherers, it could scarcely be so from the nature of their life, though it is of food-producers as it emphasises status and self-esteem.

Violence is claimed to be an abnormal form of behaviour among food-gatherers: and where, as in Australia, it occurs between the moieties of a dual organisation it is assumed that the organisation has been introduced; the dual division of society is accompanied from India to eastern Polynesia by a continued hostility between moieties. The earliest food-producing communities had their violent forms of behaviour strictly canalised. This violence is centred round the ruling groups, human sacrifice and associated institutions; naturally, head-hunting and human sacrifice produce feelings of revenge which leads to further bloodshed. It is asserted that it can be shown that the intensified warfare of peoples of low culture has been the result of contact with civilised people.

These are some of the themes dealt with by Dr. Perry. He also draws examples of the getting

of life, the age of the gods, the four quarters in heaven and earth, the immortal gods, and other high matters from peoples all over the world and from savage or barbarian conditions to the high cultures of the East, all of which originally were derived from Egypt. Even in Egypt no fundamental advance was made after the formulation of the propositions of the pyramid texts. Later developments in Egyptian theology consist of an elaboration of ideas already in circulation, but even with this apparent paucity of invention in later times, Egyptian religious thought seems to have dominated that of other peoples throughout the ages.

The activities of mankind are usually dominated by tradition, and this preserves the continuity of social institutions; but it does not occur to mankind as a whole to inquire into the reasons for social institutions, even when they are dissociated from practical utility or operate to the detriment of many members of the community. Tradition often blinds men to the obvious, and perverts their intelligence. Perhaps Dr. Perry has some excuse in adding that even scientific views are often accepted because they come from a trusted source, and it requires a stubborn spirit to maintain intellectual integrity.

Non-Religion of the Future

Psychology and Religion: a Study by a Medical Psychologist. By Dr. David Forsyth. Pp. ix+221. (London: Watts and Co., 1935.) 7*s*. 6*d*. net.

THE opinions of a distinguished psychiatrist upon the relations of psychology and religion are of great interest and importance. Dr. Forsyth's views are quite definite: religion and science, whether psychological or other, are quite incompatible with one another, because they involve two entirely different points of view. Religion is based on 'pleasure thinking', that is, on fantasy, while science is based on 'reality thinking'. Religion in short is concerned with illusions and not with reality, and belongs, properly speaking, to the infancy of our race, and not to its maturity, and so 'should be superseded in the present stage of civilisation'.

Dr. Forsyth holds that much of the imaginative power of individuals is at present wasted in the unprofitable 'pleasure thinking' associated with religion, and that if it were not dissipated in this way, but 'purposely linked to science', it might be far more beneficial to humanity. Though at the same time he would allow this imaginative power, as at present, to be devoted to the creative arts. "Science alone does not fully satisfy, and few are not the happier and better by turning from it at times, to passively enjoy the creative activities of others in books, music, and other forms of art".

It is to be doubted whether artists and those seriously interested in their work would agree to this relegation of art to the status of a recreation provider for tired men of science and professional or business men. The artist, no less than the scientific student, regards himself as establishing contact with truth; his primary function is not to amuse people, but to enlarge their perceptions of reality.

Dr. Forsyth raises many interesting questions, and is perhaps on occasion too optimistic about the benefits that science is likely to bestow. It is indeed true that a world *wholly* guided by science would be "free from intolerance such as has marred the old religions". But when will the world be so guided, and not by the economic and political prejudices which have displaced religious? It is a bad sign that though religion has declined, intolerance in Europe has increased.

Dr. Forsyth adumbrates the revolutionising not only of our educational system, but also of the relations of parents and children, by the new psychological knowledge. The patriarchal basis of our culture does indeed seem to be giving way. Dr. Forsyth is no sentimentalist, and it would have been interesting to hear from him what is the particular neurosis lurking behind the unbalanced child-worship which has now become common. Is it failure to face the problems of maturity, and a consequent flight back to childhood?

Quite half of Dr. Forsyth's book is taken up with an examination of the relations between traditional Christianity and science. His analysis, both historical and psychological, is certainly very damaging to the traditional position. But is religion necessarily to be identified with a supernatural revelation, any more than art or science —which in primitive times were both regarded in that light, but are so no longer? And cannot psychology be used to 'debunk' science and art as well as religion?

But these are big questions. Within the limits he has set himself, Dr. Forsyth has written a very useful book.

J. C. H.

The Interpretation of Science

(1) Science in the Making
By Gerald Heard. Pp. 267. (London: Faber and Faber, Ltd., 1935.) 7*s*. 6*d*. net.

(2) Science and the Public Mind
By Benjamin C. Gruenberg. Pp. xiii+196. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 12*s*. net.

IT has become clear to most thoughtful observers that science itself has reached a crisis no less pregnant than the crisis which developed in the world at large in great measure as the culmination of the rapid and uncontrolled application of mechanical invention and discoveries in physical science. Science is being driven to help to work out a broader philosophy and to combine to make a whole of life or to accept limitations on its own restricted fields of inquiry. The restrictions being imposed under modern dictatorship are merely a foretaste of what will develop more generally, if science does not support reason and assist the other faculties which are needed to establish reason and elaborate a philosophy in which reason is not merely an accident, and understanding, judgment, impartiality, charity as well as tolerance, insight as well as analysis, are absolutely valid.

On the other side, science continues to change our lives and transform almost every condition of living. New forces are continually being released, and unless we can reach an adequate understanding of the new focus science has given us, civilisation will be smashed because we continue to use the new powers for old aims. Only the discovery of superhuman purpose can make man safe against himself when armed with his present superhuman powers.

The closing, in this way, of the gap between our rapid scientific advance and our moral and ethical development demands two things. First, the breakdown of the barriers between the different sciences so as to facilitate co-ordination and secure advance where it is most needed in the interest of the whole race. Secondly, the interpretation of science to the general citizen so that he can visualise scientific advance as a whole and understand its bearing upon the other values and activities of life upon which it impinges and with which he is engaged.

(1) Both tasks demand interpreters and it is the merit of Mr. Gerald Heard's book that, although addressing himself primarily to the layman, he to some extent performs the first task also. In fact, whatever claims the original broadcast talks, on which the book is based, may have had to the title "Science in the Making", in their expanded form, the title is clearly a misnomer. There are no descriptions of technique and singularly little indication of the way in which science is built up; the book would have been more happily entitled "The Interpretation of Science". Despite a style which some will find mildly irritating, Mr. Heard has done his work well, though his references to Leakey's theories might have been more guarded. He has at any rate pointed the way, and the book may well inspire some scientific specialists to take a greater interest in science as a whole and in a scientific attitude to life in general. Is it too much to hope that it may induce others to consider more closely the social consequences of their work and to attempt its interpretation?

(2) "If society is to maintain its health and sanity, the public at large must either be trained to accept the guidance and direction of a special class . . . or else it must be trained to take part in the knowledge, the culture, the thought, the concepts upon which its civilisation rests." In these words, Dr. Gruenberg indicates the real choice before us in regard to educational policy and his own reason for presenting his study of the place of science in relation to adult education.

Although much of the material is drawn from American sources, the breadth of vision and the extent of the survey give this book real value to all who are concerned with the problems arising out of the impact of scientific discovery on society and our ability to master the new forces placed at our disposal. Dr. Gruenberg gives an admirable and concise statement of the problems which are involved in the education of society as a whole as to the value of science and its true contribution in thought and life. Whatever may be the fate of democratic government, its fullest possibilities can only be realised through a community thinking continuously and effectively according to the essential scientific method, with all that it implies of wide and clear vision, the recognition of the need for inquiry upon great questions and the settlement of problems upon the basis of facts and logic.

Scientific workers who have any concern with the interpretation of the results of scientific investigations to the community or with the consequences of their own discoveries cannot fail to find Dr. Gruenberg's analysis of the situation highly suggestive whether in treating of the failure of science to reach the public, the means and methods of bringing science before the public, or in his recommendations for future efforts in this field.

R. BRIGHTMAN.

Sociology in the United States

Race and Culture Contacts

Editor: E. B. Reuter. Contributors: Romanzo Adams, W. O. Brown, E. Franklin Frazier, Max Handman, Asael T. Hansen, J. O. Hertzler, Charles S. Johnson, Andrew W. Lind, R. D. McKenzie, Robert E. Park, John A. Rademaker, Edward B. Reuter, Jesse Frederick Steiner, Clark Wissler. Pp. viii+253. (New York and London: McGraw-Hill Book Co., Inc., 1934.) 18*s*. net.

IN the United States, students of racial questions have the advantage—or disadvantage according as it is regarded—of finding their problems very much at their doors. This undoubtedly is responsible for a characteristic realism in approach, which finds extreme expression in a marked addiction to questionnaires, but, at the same time, is not always conducive to academic calm and detachment in discussion. As might be expected, however, anything in the nature of racial feeling is commendably absent from the papers which compose this volume. On the other hand, more than half the contents is taken up with the consideration of conditions which directly affect the United States, specific problems in the social structure of to-day. This is not without significance in a book which is intended for a wider public than the professional audience to which the papers were originally addressed.

Prof. Reuter has selected for inclusion in his volume fourteen of the papers which were presented at the twenty-eighth annual meeting of the American Sociological Society, prefacing them with an introductory chapter in which he outlines for his non-professional readers certain general considerations. In his selection, he has been influenced by the fact that most of the communications which follow—in fact all with one exception—are descriptive and historical, rather than theoretical, in character. They are arranged in a logical order, which follows the sociological argument of equilibrium—contact—maladjustment—equilibrium. Hence the papers fall more or less into two groups, an earlier which covers the beginnings of racial contact and conflict and is concerned largely with Old World conditions, and a second in which, as already mentioned, are described the adjustments partial or complete of American contacts—Negroes, Orientals settled in America and Hawaiians; Prof. Clark Wissler, in an able analysis of development in pioneer days affecting the culture and status of the American Indian, occupying something in the nature of an intermediate position.

In the first and more general section, it must not be held invidious to select for mention two papers, one a general survey of conditions in three continents by Mr. Robert E. Park, which is of especial interest to British readers for what it has to say of South Africa and India, and a study by Dr. Max Handman of adjustments between conflicting elements as exemplified in Transylvania.

Turning to the papers dealing with problems directly affecting the United States, English readers will find much here to interest them, written from an intimate point of view and with authority. One fact immediately calls for notice. That is the effect of the common school system. Both Mr. J. F. Steiner and Mr. John A. Rademaker, who deal with the settlement of Orientals in the United States, agree that, notwithstanding the difference in attitude of the first generation of Chinese and Japanese, the former still clinging to the tie of their native land, the racial barriers between American and Oriental tends to break down in the second generation under the influence of the association in early life at school.

Educational influence is also affecting the Negro problem, though in a different way. Mr. C. S. Johnson points out how the rising generation is now bringing about a modification in the Negro outlook, and it is probable that this is the influence which is largely responsible for the grades into which Mr. E. Franklin Frazier classifies the types of Negro family. His paper is a very interesting study of what is in effect a society within American society, which is governed by an entirely different social code. Mr. Frazier finds four types of Negro family organisation, of which, that which for purposes of distinction might be called the primary form, is purely matriarchal on primitive lines, the man being entirely absent or unimportant. This, however, is not a relic of an African matriarchal system inherited from slave ancestors, but a survival of pre-emancipation days, in which conditions, economic and social, favoured and tended to stabilise the position of the woman in independence of her male Negro consort. Post-emancipation conditions perpetuated this state of affairs, except in the case of the more skilled or well-to-do men.

The volume closes with a contribution by Mr. A. W. Lind on Hawaii, carrying further evidence in an earlier essay by Mr. Romanzo Adams. Both point to the conclusion that in Hawaii racial contacts have reached a phase of equilibrium,

although not without a note of warning that naval and other professional or official gradings may introduce a note of disharmony. Historical causes, which are here ably analysed, have brought it about that in all personal associations racial feeling is entirely absent. Americans, Hawaiians and Orientals associate on equal terms and without afterthought. Thus the book closes with the comforting thought for the practical sociologist that in one spot, at least, in a world-wide survey, a solution of the racial problem seems to have been attained.

A Psychology of Conduct

The Psychology of Wants, Interests and Attitudes By Edward L. Thorndike, and the Staff of the Division of Psychology of the Institute of Educational Research, Teachers College, Columbia University. (Century Psychology Series.) Pp. x+301. (New York and London: D. Appleton-Century Co., Inc., 1935.) 10*s*. 6*d*. net.

IT seems perfectly obvious that factors which in common conversation are called wants, interests, attitudes, desires, motives, tendencies and feelings influence human action, and perhaps the behaviour of all animals, more powerfully than any others. For many reasons, however, factors of this kind are not easy to study experimentally in an adequately controlled manner, and comparatively little is known definitely about the ways in which they operate. Many years ago, Prof. E. L. Thorndike began to develop an experimental technique for studying these 'satisfiers' of action, as he now calls them, and he soon arrived at the view that they operate, not only in a prospective manner, tending to establish connexions between particular reactions in a series, but also, retrospectively, strengthening or weakening connexions once set up. In this book he, and a number of his students, present and discuss the results of their most recent studies of the general problem of the effects of specific tendencies upon behaviour.

A want may lead a person to act in a specialised manner the very first time it is aroused. But when the same want has been aroused a hundred times, the resulting action may be very different. This difference, Thorndike says, is due to two things: the backward influence of the want, and changes in the wants, and connexions of wants, themselves. These are his two main problems: how can wants, interests and attitudes act in a backward way upon the series of acts which satisfy them? Also how are they "strengthened, weakened, and shifted in their attachments"?

It is not possible, in a brief notice, to describe in any detail the mass of ingenious experimental dodges used by Thorndike and his collaborators. All of them in this book concern human action, and particular questions asked and answered are: How does a want determine what response a situation is going to evoke? How does it settle what response is going to survive? What is the precise influence of reward and punishment? Is there any real difference between learning to know or to do things that are valuable and things that are useless? It is now regarded as more than ever certain that wants, and the like factors, do somehow work backward, strengthening the bonds between acts that lead to their satisfaction. Further, some progress is made with the job of saying in detail how they do this, though the physiological mechanism involved—and Thorndike is quite sure that there is one—remains obscure. Apparently punishments are not of vast direct significance, though they can turn aside the agent to some course of action that is a genuine 'satisfier'. The experiments on the direct influence of interests on learning and doing are perhaps a little less convincing than some of the others, but from them it appears that the common belief that interest aids both is justified, but exaggerated; while if interest is present, whether what has to be learned is useful or not seems to make very little difference indeed.

The second part of the volume, dealing with the changes that may take place in wants, interests and attitudes in the course of experience, is not less important than the first. Again, rewards bulk largely in the discussion. What is the effect of a reward, near, or remote, emphatic, or weak? How are wants affected by being tied up with particular stimuli and situations by a conditioned reflex method? What precisely happens when a stimulus, being unpleasant, is nevertheless often repeated? A final chapter discusses difficulties in the education of wants, interests and attitudes, and appendixes give adequate samples of the experimental methods used throughout, and their results.

The volume as a whole is an extraordinarily interesting piece of pioneering work. It is original, both in design and in execution. It should point the way to a host of investigations, by relatively controlled methods, of intensely important theoretical and practical questions which hitherto have been mainly merely a field for conflicting speculations.

F. C. B.

Fracastor's Poem on Syphilis

Fracastor: Syphilis, or the French Disease; a Poem in Latin Hexameters
By Girolamo Fracastoro. With a Translation, Notes and Appendix by Heneage Wynne-Finch. Pp. vii+253+4 plates. (London: William Heinemann (Medical Books), Ltd., 1935.) 10*s.* 6*d.* net.

IN the introduction to this scholarly work, which admirably illustrates the close relation of medicine with literature, Mr. James Johnston Abraham, who is not only a well-known specialist in venereal diseases but also a writer of distinction, gives a short sketch of the life and times of Fracastor, and the origin and treatment of syphilis from the time of Fracastor until the present day.

In the preface to his translation, Mr. Heneage Wynne-Finch lays stress on the literary charm of the poem, which he declares has lately been neglected or obscured, though he admits that Fracastor occasionally indulges in tedious repetitions and redundancies. The poem, however, received the highest praise from contemporary writers such as Cardinal Bembo, the Venetian poet, to whom it is dedicated. Moreover, the popularity of the poem is shown by the fact that after its first appearance in 1530 at Verona, thirteen editions were published in the course of the sixteenth century.

Of Mr. Wynne-Finch's translation, which, unlike Natum Tate's verse rendering of 1686 is in prose, it may be said that he has admirably succeeded in his aim of retaining the grace and charm of the original, while keeping fidelity to the text.

The poem, which consists of three books, relates how a shepherd named Syphilus incurred the wrath of Apollo, who punished him by the infliction of a highly contagious and terrible new disease. A vivid description of the hideous sores and deformities of the unhappy victims is given in the first book, while the last two are mainly devoted to treatment, particularly by guiacum, on which Ulrich von Hutten had lavished such undeserved praise, and mercury.

The translation is followed by an essay on Fracastor and Virgil by Mr. Vernon Rendall, who illustrates by numerous examples Fracastor's use of Virgilian idiom and language as well as his resemblance to his master in his appreciation of the beautiful Italian country. Like Mr. Wynne-Finch, however, Mr. Rendall is not blind to Fracastor's shortcomings, and notes particularly the servile manner in which he takes incident and detail as well as words and phrases from the "Æneid". Mr. Rendall has also assisted Mr. Wynne-Finch in the preparation of copious notes on the poem, which include an abridged translation of the chapters on syphilis in Fracastor's other most important work, "De Contagione".

The book, which should appeal to all who are interested in the history of medicine or literature, is illustrated by portraits of Fracastor, facsimiles of pages from the first edition and first English translation and woodcuts of fifteenth century works on syphilis.

Penetrating Ocean Depths

Half Mile Down
By Dr. William Beebe. Pp. xix+344+88 plates. (London: John Lane, The Bodley Head, Ltd., 1935.) 18*s.* net.

DR. WILLIAM BEEBE is the born adventurer. To him the thrill of arriving where man has never arrived before is an unfailing stimulus to further exploits. When he turns from the tropical jungle and the desert to the ocean he does not rest until, inside a hollow steel ball, he has penetrated its depths to a distance of 3,028 feet beneath the surface. Even as he is making his hazardous journey down into the unknown the messages he sends along the telephone line to the surface reveal the driving spirit of the venture:

"We have just splashed below the surface."	
"We are at our deepest helmet dive."	60 ft.
"The *Lusitania* is resting at this level."	285 ft.
"This is the greatest depth reached in a regulation suit by Navy divers."	306 ft.
"We are passing the deepest submarine record."	383 ft.
"The *Egypt* was found at this level by divers in rigid shells."	500 ft.
"A diver in an armoured suit descended this far into a Bavarian lake—the deepest point which a live human has ever reached."	525 ft.
"Only dead men have sunk below this."	600 ft.
"We are still alive and one-quarter of a mile down."	1,426 ft.

Dr. Beebe is also a talented writer, so that when he comes to record his experiences, his free and personal style of presentation ensures the production of a readable narrative. There are few who cannot enjoy a well-told story of adventure.

In his latest book, "Half Mile Down", however, Dr. Beebe would seem to wish to draw the reader aside from the material facts of scientific adventure under sea in order to contemplate the æsthetic delight of such work. He therefore starts with an extract from William Morton Wheeler's "Entomologist in Hades" as his Apologia, in which the 'correct' investigator with his constant striving to solve 'problems' is contrasted with the amateur who is "permitted to roam at will among the fragrant asphodels of the Elysian meadows, netting gorgeous, ghostly butterflies until the end of time". And in the arrangement of the text he creates four divisions, the first of which is entitled "Emotional", and the last "Technical". Even so, before seven pages of the text are completed, the uncontrollable spirit of the real adventurer breaks out once more and Beebe is telling us that "in my present existence there is only one experience left which can transcend that of living for a time under the sea—and that is a trip to Mars".

In these circumstances the book is a difficult one for the reviewer. For it is neither a straight story of adventure under sea, nor a scientific manual, but rather an odd admixture of fact and imagination. Nevertheless, it may be said to consist of a popular narrative, complete in the first 225 pages, and a series of technical appendixes, filling the remaining one hundred or so pages to which the student may turn for the more prosaic scientific data of exploration. There is much to interest everyone in the narrative, including a history of deep-sea diving from ancient times to the present day, and there are many fine illustrations and reprints. The eight technical appendixes deal with the construction of Mr. Barton's original bathysphere of 1930 and its modifications in 1934; a bibliography of the history of diving; a catalogue of unedited telephone observations made during actual dives of the bathysphere; a classified résumé of organisms observed; and a final summary of conclusions relating to physical conditions at the greatest depths, temperature, pressure, clarity of observation, and biological observations on the abundance, illumination, activity, size and vertical distribution of oceanic organisms.

A Modern Description of World Vegetation

Pflanzengeographie auf physiologischer Grundlage

Von Prof. Dr. A. F. W. Schimper. Dritte, neubearbeitete und wesentlich erweiterte Auflage, herausgegeben von Prof. Dr. F. C. von Faber. Band 1. Pp. xx+588. Band 2. Pp. xvi+589–1612. (Jena: Gustav Fischer, 1935.) 90 gold marks.

TWO books published at the end of last century undoubtedly laid the foundations of modern plant ecology—Warming's "Plantesamfund", made available to the majority of international readers through Knoblauch's German translation published as "Lehrbuch der Oekologischen Pflanzengeographie" in 1896, not appearing in English until much later (1909) in an enlarged but not nearly so satisfactory a form; and the original edition of the work under review, Schimper's "Pflanzengeographie auf physiologischer Grundlage" (1898), which was fortunately translated into English with less delay (1903). The two authors presented their material from somewhat different points of view, but both were masters of their subject, both had travelled widely in the tropics as well as in temperate regions, and both gave thorough systematic accounts of what was then known of the field. Warming's book was quite short, unillustrated and adopted a somewhat limited, though thoroughly instructive, guiding principle. Schimper's was much longer, more discursive, illustrated by a great number of excellent photographs of vegetation and drawings of characteristic plants, and was indeed at the time of its publication a veritable mine of information previously unavailable to the student. It was somewhat vitiated, however, by certain physiological theories which have proved untenable in the light of later research.

It would be difficult, and not relevant here, to attempt to estimate the relative influence of these two books on the subsequent development of the subject. Together they have stimulated innumerable investigations, and have formed worthy foundations for the immense, though still rather inchoate, superstructure that has been built upon them during the last thirty-five years. There have also, of course, been other creative influences at work, of which the most important has been the increasing conviction of the universal validity and fundamental importance of the 'succession' or 'development' of vegetation, which we owe mainly to the work of the American ecologists, Cowles

and Clements. At present, there is great activity over the whole field almost throughout the world, not least in the Continental countries, in almost all of which there has been a notable revival of interest since the War, largely due to the influence of Braun-Blanquet.

The fundamental value of the modern type of work for application to the great practical problems of land utilisation, recognised many years ago in some countries, for example, the United States and New Zealand, is being slowly—much too slowly—appreciated in the British Empire. It is not too much to say that if this kind of work were adequately endowed, actively prosecuted and the results properly applied, the avoidance of wasteful exploitation of land in 'new' countries would eventually represent a stupendous saving in money alone. Ecological survey is in fact the pre-requisite of that intelligent 'planning' on a large scale which is becoming more and more urgently necessary in the modern world.

Prof. von Faber has now presented us with a new, greatly enlarged, and almost completely rewritten edition of Schimper's great work, taking into account the immense number of investigations which have been carried out during the present century. He has maintained the general plan of the original book, beginning with a description of 'ecological factors', to which 260 pages are devoted. This is a good and fairly thorough, if rather pedestrian, account, in which the more modern work is adequately treated. The author then proceeds to consider the major units of vegetation, the so-called 'plant formations'. Here he maintains Schimper's distinction between climatic and edaphic formations, and ignores the views of Clements, who considers that edaphic formations are always stages in the development, or modifications, of the climatic formations. Prof. von Faber says that the controversies about the units of vegetation and their terminology are mainly controversies about names. That is partly, but not wholly, true: some of the differences arise from real differences of interpretation due to our still inadequate knowledge of the facts. The author's very brief treatment of succession, sound so far as it goes, is quite inadequate.

The third and much the longest section of the book, occupying no less than 1,200 pages, is devoted to a systematic description of the vegetation of the world and the factors which determine its multiform variations. Beginning with the tropics, of the vegetation of which Schimper's original work was the first general scientific treatment, and to which Prof. von Faber's own observations have contributed considerably, we pass to the temperate and finally to the arctic and alpine regions. Though we are still extremely ignorant of the detailed ecology of tropical vegetation, our knowledge, particularly of the physiology of tropical plants, has very greatly increased in recent years, and the author's account, both of this and of the general relations of vegetation to the characteristic tropical climates, is by far the best which has appeared. Our actual knowledge of the detailed constitution of the most characteristic of all—the equatorial rain forest—is now being put on a firm basis by the work of Mr. Paul Richards, who is at present following up his thorough investigations of small samples in British Guiana and Sarawak by studies in West Africa.

When we turn to the vegetation of temperate regions, we find Prof. von Faber's account, as was almost inevitable, far less satisfactory, though it includes a number of valuable discussions and summaries. An adequate handling of the enormous quantity of material provided by the studies of innumerable observers in Europe and North America is very nearly an impossible task, not merely on account of its sheer bulk, but also mainly because the observations have been made from so many different points of view, with widely varying accuracy, thoroughness and technique, so that very many of the results cannot be correlated and unified. We cannot complain that the author has neglected the literature. Though his citations are necessarily and confessedly far from being exhaustive, he has referred to a great range of representative work in all the principal countries. But the result leaves a somewhat confused and chaotic impression on the mind, and that is not surprising. Probably the only effective way to write a scientific description of world vegetation would be to adopt a specific point of view, and to neglect all work which did not provide data suitable for its elaboration. The active and widespread work of Braun-Blanquet's school is in this direction, though some of us may be a little sceptical as to the complete soundness of its foundations.

With minor mistakes and misapprehensions in so large a book—and many such the most indefatigable and accomplished author could scarcely be expected to avoid—it is naturally impossible to deal, but we regret to see that in the world map showing the distribution of the main types of vegetation the British Isles is even more fantastically divided than in most of the maps published by Continental authors. The book is illustrated by three folding maps and 613 figures, mostly beautiful photographs of typical vegetation excellently reproduced. When all criticisms have been made, Prof. von Faber's edition of Schimper remains an exceedingly valuable work, which will be indispensable to all students of the subject.

A. G. Tansley.

Shellac

Shellac: its Production, Manufacture, Chemistry, Analysis, Commerce and Uses
By Ernest J. Parry. Pp. xi+240. (London: Sir Isaac Pitman and Sons, Ltd., 1935.) 12*s*. 6*d*. net.

THE insect that produces the resinous material which is called shellac takes little heed of the notoriety with which its product is now invested. Financial crises of considerable magnitude have attended the failure of speculative attempts to corner the market in it, and the word has been in the mouths of thousands who have little, if any, knowledge about the material, its manufacture or its uses. It is permissible to comment on the fact that most raw materials, the production of which is limited, are liable to have the supplies cornered by vested interests and their price to the user raised accordingly. Once, however, a chemical synthesis of such materials or of a substitute for them has been achieved, the danger of a monopoly is at an end and the product can be produced in quantity without restraint, except such as arises from patent laws, and sold at a cost which bears close relation to the cost of manufacture. The urge to make synthetic products is thus a proper one economically, though, alas, the competitive struggle between natural and synthetic has often resulted in the ruin of an industry and much unemployment.

The lac industry began with the demand for the dye, the crimson lake or cochineal of commerce. Coal tar dyes superseded this; but fortunately the resin was found to be valuable first as a varnish, then as an electrical insulating material, and later for gramophone records.

Mr. Parry, who is an analyst of repute, has given us a book of wide interest covering the whole of the divarications of his subject. Starting with the origin, a full account is next given of the practical production, the enemies of the lac insect and the manufacture of shellac. These sections are well illustrated.

When shellac has reached the market, the question arises of its evaluation by analysis, and it is only in quite recent years that this has been possible. Mr. Parry now treats the question at considerable length, indicating a procedure for the commercial analysis. When it comes to the chemistry of shellac, we are on less certain ground, particularly as it is a mixture, being said to consist of two parts of shellolic acid, five parts of aleuritic acid and seven parts of amorphous acids. Formulæ have been suggested, particularly by Harries and Nagel, for these two acids.

The chapter on the commerce of lac introduces a number of subjects, such as the rights of landowners in India, marketing up to the Calcutta merchant shippers, the London trade, contracts: the expert must know something of all these. In an appendix, the author's original papers are included, largely dealing with adulteration, also the United States standards and methods of analysis, and finally a glossary of native terms.

Information is thus provided for every branch of the industry, and the seeker for knowledge about shellac is well cared for: he will, or should be, properly grateful to Mr. Parry for the trouble he has taken in making his own unique store of knowledge generally available. E. F. A.

Photoelectricity and Surface Chemistry

Electron Emission and Adsorption Phenomena
By J. H. de Boer. Translated from the manuscript by Mrs. H. E. Teves-Acly. (Cambridge Series of Physical Chemistry.) Pp. xi+398. (Cambridge: At the University Press, 1935.) 21*s*. net.

IT is surprising that there are so few books in English which deal with photoelectric phenomena. Hughes and Du Bridge's book, which made a welcome appearance three years ago, deals mainly with those aspects which are of special importance to physicists, and the only other book which has appeared recently concerning this or related subjects is Reimann's "Thermionic Emission". Dr. de Boer is therefore to be congratulated on giving us another account of this interesting subject from a novel point of view.

The object of this book is the interrelation of the adsorption of atoms on solids and the photoelectric and thermionic emission of electrons. The first two chapters are introductory, and give a short summary of the fundamental phenomena. The next part of the book is concerned with the effect of adsorbed layers on the emission from metal surfaces, while the last part deals with the photoelectric effect in insulators.

The change in the work function due to adsorbed layers is familiar ground, and Dr. de Boer has covered it well. The use of potential curves greatly

simplifies the presentation, though there is always the danger that one is tempted to seek explanations by drawing suitable potential curves instead of performing calculations, especially when the calculations are difficult. The advantages of such curves do, however, outweigh any disadvantages which their abuse might bring. This section of the book closes with discussions of the absorption of light by matter in the adsorbed state and of the selective photoelectric effect. Both these chapters are well and critically written, but occasionally one meets categorical statements on questions which are still undecided. For example, it is stated two or three times that the selective effect is an atomic effect, due to the absorption of light by the adsorbed atoms, and it is not until § 71 is read that one realises that this is merely the author's own opinion. Admittedly nearly everyone would agree that the selective effect is to be explained in this way, but this is not because the explanation fits all the facts, but because no other hypothesis seems tenable. At the moment, it is difficult to understand the enormous difference in the action of light polarised in, and perpendicular to, the plane of incidence. If the selective effect is an atomic photoelectric effect there should be no such great difference, and, on the other hand, if it is caused in any other way, it is not easy to explain the high yield of electrons.

There are three very readable chapters on photoconductivity in insulators. This difficult subject seems to become more complicated every year, and it is extremely useful to have an up-to-date account. The author takes a rather optimistic view of the subject, which is only natural in an experimental physicist. There is bound to be a certain amount of chaos when the phenomenon depends on the presence of small quantities of impurities, and perhaps the experimenter sees more of the order, while the theorist sees more of the chaos. The last three chapters discuss rectifiers and the photoelectric and thermionic properties of surfaces covered with thick layers of dielectric.

The book is a stimulating one, and should help those working on one of the subjects to appreciate what information other lines of attack can yield. The translation has been carried out adequately.

A. H. Wilson.

Binary Stars

The Binary Stars

By Robert Grant Aitken. (McGraw-Hill Astronomical Series.) Second edition. Pp. xii+309. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 21*s*. net.

When, a few months ago, Dr. Aitken retired from the directorship of the Lick Observatory and from active observational work, he had completed forty years of observation and study of binary stars. During this time he had carried to completion a survey, commenced in conjunction with Prof. Hussey, but carried on single-handed from 1905, of all stars down to magnitude 9·0 on the B.D. scale and north of 18° south declination, for the discovery of double stars; he had discovered more than 3,000 double stars with a separation not exceeding five seconds of arc; he had remeasured most of these stars, after suitable intervals, at two later epochs for the discovery of orbital motion, and had also made a considerable number of measures of known binaries. In addition, he had computed many orbits and had completed the preparation of a new general catalogue of double stars. Seldom can the energies of a lifetime have been devoted more continuously and enthusiastically to the advancement of one chosen branch of astronomy.

It is appropriate that almost the last work of Dr. Aitken before his retirement was to pass the proofs of the second edition of his monograph on the binary stars. The first edition had long been out of print, and the large amount of observational and other work in double star astronomy had made it in large part out of date. This work is well known as an authoritative and comprehensive account of all aspects of the subject. The new edition follows closely along the lines of the original edition, which has been thoroughly revised and brought up to date. The historical account of the subject is of great value and of general interest, whilst the chapter on observing methods is full of sound advice for double-star observers. Emphasis is placed on one precaution that has characterised Dr. Aitken's own observing and that has application outside this particular field: "The most important precaution to be taken in double-star observing is quite independent of instrumental adjustments. It is *to make measures only on nights when the observing conditions are good*. . . . I make this statement with all possible emphasis." Methods of orbit computation, not only of usual binary systems, but also of spectroscopic and eclipsing binary systems are described. Of special value for purposes of reference are two tables containing the elements of determined

orbits of both visual and spectroscopic systems, the authority for each set of elements being given, with a reference to the original publication.

The extensive double star surveys in both hemispheres have provided material for statistical discussion much more complete than when the first edition was published. It must have been with considerable satisfaction that Dr. Aitken was able to repeat without essential alteration the general summary given in the first edition of the more important conclusions to be drawn from the statistical material. One conclusion is of particular interest in connexion with the origin of binary systems: that there is an unbroken progression of series of orbits from systems with a period of less than a day, revolving about each other almost in contact in circular orbits to systems with periods of hundreds or thousands of years, moving in highly eccentric orbits with axes many hundreds of times the distance of the earth from the sun. The inference is that a common origin must be sought for all binary systems, and that no theory yet advanced to account for the origin and subsequent development of binary systems can be regarded as satisfactory. Down to the magnitude limit of Aitken's survey, about one star in eighteen is seen as a visual binary with the 36-inch telescope; of the naked eye stars, about one star in seven is a spectroscopic binary. The properties of binary systems is thus so high that the formulation of a satisfactory theory of their origin is one of the most important unsolved problems of cosmogony.

Short Notices

Archæology and Ethnology

The Folklore of Morocco

By Dr. Françoise Legey. Translated from the French by Lucy Hotz. Pp. 277+25 plates. (London: George Allen and Unwin, Ltd., 1935.) 12*s*. 6*d*. net.

Moroccan folklore, as Dr. Westermarck has shown us, is essentially a composite product. A veneer of the Moslem creed overlies a solid body of Berber magical practice and belief, in which survivals from the old Roman province are embedded like plums in a pudding. The genie, whether good or bad, common to the whole Moslem world, claims attention equally with the mysterious *baraka*, the mystic individual power of the animate and inanimate world, which is characteristic of Morocco, while in the ever-present fear of the evil eye the inhabitants affirm their Mediterranean descent.

This composite character of Moroccan belief is well illustrated in the material collected by Mme. Legey during the thirteen years of her acquaintance with Morocco, although she purposely refrains from comment on comparable beliefs and the like elsewhere. As a medical officer of the French administration, her duties and her sex have given her access to sources of information from which the ordinary observer is barred. Her record of the beliefs and practices connected with disease and its treatment and the feminine province in matters affecting birth, infancy, adolescence, marriage and its ceremonial, will be found especially valuable.

Although Mme. Legey covers the whole field of belief from ideas relating to the creation and character of the cosmos to the reverence paid to the deceased holy man at his burial-place, her contribution to the subject is most considerable in medical matters and in what is specifically the woman's world. The index, unfortunately, is not adequate to the subject-matter.

The Hill Bhūiyās of Ōrissā: with Comparative Notes on the Plains Bhūiyās

By Sarat Chandra Roy. Pp. v+320+xxxviii+17 plates. (Ranchi: *Man in India* Office, 1935.) 8 rupees.

This is the fifth volume in a series of monographs on the aboriginal tribes of India, which Sarat Chandra Roy has in course of preparation, on a foundation of twenty-five years experience of the peoples of the central hill belt. The present volume is concerned with one of the few tribes which show in their different branches all the various stages of evolution from the wild tribes of the hills to the thoroughly Hinduised *zamindars* of the plains, some of whom have now progressed so far as to claim Rajput or Kshatriya descent. They are distributed widely over half a dozen provinces—Bengal, Bihar, Orissa, Chota Nagpur, Assam, the United Provinces, Central Provinces and Madras. Here, however, the author deals mainly with the hill tribes who, as he notes, are correctly classified in the last census as Kolarian. Culturally, they are Pre-Dravidian.

Biology

(1) Living Things: an Introduction to Biology

By Richard Palmer. Pp. 400. (London: George Allen and Unwin, Ltd., 1935.) 7*s*. 6*d*. net.

(2) The World of Nature

By H. C. Knapp-Fisher. Pp. iv+512. (London: Victor Gollancz, Ltd., 1935.) 6*s*. net.

(1) In being a true biology, "Living Things" makes a definite claim to freshness, and thus commands the attention of teachers. Animals and plants are in close conjunction with each other, and the author makes no attempt to segregate them artificially. Of course, this is how they should be treated:

nevertheless, the author is to be congratulated in having done what many biological authors have neglected to do.

Another fresh note is the chapter on the methods of science, which, if read by the discriminating student before and after reading the rest of the book, will prove invaluable in giving the reader the most desirable outlook on the subject. Apart from this common-sense, and therefore correct, method of treatment, it may be said that the book has an attractive style and is comparatively well illustrated. It can be whole-heartedly recommended to students up to matriculation standard.

(2) "The World of Nature" makes a different appeal: but its standard is equally high. It is more a natural history than a biology, and is written to make the world of Nature "intelligible to the ordinary educated person". We venture to say that it will not only do this, but it will also prove to the sceptical and disinterested what a fascinating field for cultural interest lies around them. There is only one criticism —a selfish one perhaps—that is, we would wish to see more of the unique but brilliantly executed illustrations.

The Botanist in Ireland

By Dr. Robert Lloyd Praeger. Pp. xii+497+44 plates. (Dublin: Hodges, Figgis and Co., 1934.) **12*s.* 6*d.***

THIS volume is difficult to classify. It is not a Flora; it is not a guide book; it is not a scientific treatise on Irish phytogeography; yet it combines features of all these into a homogeneous whole and provides those interested in the Irish flora with an ideal guide and companion for their studies and their travels. No one but Dr. Praeger could have written such a work, and it is indeed a fitting crown to his life-long labours on the flora of his native land.

The work is divided into four parts. The first comprises sections on the physiography, geology, topography and climate of Ireland, each a model of compression and clear statement. The second contains notes on various miscellaneous aspects of the flora, including topographical and ecological distribution, and an invaluable list of rare or interesting Irish plants, in which information hitherto scattered in periodicals has been brought together.

The main part of the book is devoted to a topographical survey of the whole country, with a full description of the flora of each area. Dr. Praeger's intimate knowledge of every square yard that he describes gives to these pages a remarkable vividness which must be unique in botanical literature.

The concluding section consists of a census list of the flora, with the distribution of each species indicated by numbers referring to the counties in which it occurs. There is an excellent index.

The whole volume is copiously illustrated with maps, diagrams and photographs of individual plants and botanical localities. The photographs, most of which were taken by Mr. R. Welch, are extraordinarily beautiful, and add greatly to the value of the book.

Elementary Microtechnique

By H. Alan Peacock. Pp. vii+200. (London: Edward Arnold and Co., 1935.) 5*s.* 6*d.* net.

THIS small book should prove of value to the amateur and elementary biologist, and the more advanced student and laboratory worker may well add it to his reference library, for it contains a number of practical hints and useful dodges and recipes. The matter presented is concisely given, largely in tabular form. After some introductory remarks on protoplasm and cytology, the processes and principles of microtechnique and methods for making microscopical preparations are considered. A chapter follows on technique, including fixing, hardening, embedding and sectioning, staining, and mounting, with a section on bulk staining. The next chapter deals in alphabetical order with methods for specific purposes for animal and plant organisms and tissues, and contains a surprising number of headings, ranging from acarine disease of bees and annelids to *Vorticella* and yeast (rotifers do not seem to be mentioned here). The next chapter gives the use of stains, followed by one containing the formulæ.

Ink for writing on glass is not given, while grease pencils are so easily obtained that the method for making them might well be omitted. Similarly, such agents as Farrant and glycerin jelly are probably better purchased than made, and the same applies to eyepiece scales and micrometers. The remarks on numerical aperture may give rise to confusion, as the term "definition" is used, instead of the correct one, "resolution". A most useful appendix gives the sources from which the organisms and tissues mentioned may be obtained, and their preservation is dealt with in another appendix.

R. T. H.

Chemistry

Organic Syntheses:

an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Carl R. Noller, Editor-in-Chief. Vol. 15. Pp. v+104. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935.) 8*s.* 6*d.* net.

THIRTY substances are included in the current volume of this welcome annual. Among acyclic compounds with long carbon chains are *n*-dodecyl bromide (made from *n*-dodecyl alcohol), *n*-hexadecane (from cetyl alcohol, via cetyl iodide), and oleyl alcohol (from butyl oleate, prepared from olive oil by alcoholysis). Simple open-chain compounds include trichloroethyl alcohol, which is readily prepared by treating chloral with aluminium ethoxide in presence of anhydrous alcohol. In the aromatic series, a simple method is given for converting 2,4-dinitrochlorobenzene into 2,4-dinitroaniline by treatment with ammonium acetate and ammonia gas at 170° in an open vessel; further, an example of oxidation with selenium dioxide is provided by the preparation of phenylglyoxal from acetophenone. In the heterocyclic series, Hans Fischer submits details of the preparation of 2,4-dimethyl-3,5-dicarbethoxypyrrole and its conversion into 2,4-dimethylpyrrole,

by means of processes based upon the original procedure of Knorr.

Improved methods of making two simple reagents of wide use in organic chemistry are also included. There is, in the first place, an illustrated description of a useful laboratory apparatus capable of producing 300 grams of anhydrous hydrogen bromide per hour by the direct combination of hydrogen and bromine. Secondly, an account of Arndt's recent method for preparing diazomethane will be of service to users of this valuable synthetic reagent. Methyl urea is made from methylamine hydrochloride and potassium cyanate; alternatively, aqueous ammonia and dimethyl sulphate may replace the methylamine hydrochloride. Treatment with nitrous acid furnishes nitrosomethyl urea, which is then subjected to the action of aqueous potassium hydroxide in presence of ether. It is rightly emphasised that diazomethane is an especially insidious poison, the careless manipulation of which may induce a super-sensitive condition rendering the subject liable to attacks of asthma or fever. An appendix contains later references to preparations given in the preceding volumes. The subject index covers vols. 10–15 of the series.

J. R.

Van Nostrand's Chemical Annual:

a Hand-Book of Useful Data for Analytical, Manufacturing and Investigating Chemists, Chemical Engineers and Students. Edited by Prof. John C. Olsen. Seventh Issue. Pp. xvii+1029. (London: Chapman and Hall, Ltd., 1935.) 25*s*. net.

In the preparation of the new edition, the editor has compared the data given in the previous edition with the "International Critical Tables", and in some cases later data than those given in this publication have been used. In all cases, critically selected values are given instead of all the values published. Many new tables appear, including those of physico-chemical data, boiling points, vapour pressures and latent heats, and tables for thermal observations and calculations.

The information contained in the book is such as will normally be required in the chemical laboratory and by the chemical engineer, and the revision appears to have been thorough and satisfactory. The manual is one which may be recommended as likely to be extremely useful, and its relatively small size will enable the user to have at his command in a very convenient form a large range of material, which otherwise would have to be sought in bulky and expensive volumes not always at hand when a figure is urgently required. It is strongly bound and should stand use in the laboratory and works.

Colloidal Electrolytes:

a General Discussion held by the Faraday Society. Pp. iv+422+6 plates. (London and Edinburgh: Gurney and Jackson, 1935.) 18*s*. 6*d*. net.

The report on the Faraday Society's general discussion on "Colloidal Electrolytes", held in London on September 27–29, 1934, is noteworthy for its very wide scope, since it includes no less than 36 papers, with discussions to which a large number of speakers contributed. Attention may also be directed to an improved binding, which appears to have been rendered necessary by the expansion of the report to more than four hundred pages (as compared with about forty pages for the first of these discussions in 1907), and to the very modest price at which it has been issued. In view of the importance of the subject with which it deals, its authoritative character, and the very favourable conditions under which it is available, it may be anticipated that the report will have a wide circulation beyond the boundaries of the Society to which the credit for its publication belongs.

The Teaching of Chemistry

By N. F. Newbury. Pp. xii+247. (London: William Heinemann, Ltd., 1934.) 6*s*. net.

The young graduate who is taking up his duties in a school will be grateful to the author for the information provided in this book, and even the experienced teacher will find something useful in it. Not all the recommendations will meet with approval, and a good deal of space is taken up by statistical information which will rapidly become obsolete. The author's recommendation that the young teacher should discard his university lecture notes and rely on elementary textbooks for his material is one which should not be followed, since in this way he is likely to use a good deal of old-fashioned and obsolete material which is perpetuated in many books.

The author, like most teachers, has his preferences, and the use of microchemical methods seems to be one. He is not always consistent: on p. 140 he says the use of formulæ and equations should be "discouraged" in the first year, whilst on p. 166 he gives a "model" answer in which a formula is used by a boy who had studied chemistry only eight weeks. These are minor points of criticism. The book is on the whole a good one, and should be found useful. The lists of books recommended, however, seem to require some extension, since some popular and successful books are conspicuous by their absence.

Engineering

Piles and Pile Driving

By A. C. Dean. Pp. x+221. (London: Crosby Lockwood and Son, Ltd., 1935.) 42*s*. net.

In his introduction to this book, the author points out that the use of piles for foundations is a practice of great antiquity. Although he does not allude to prehistoric times, it may even be claimed that it dates back to the remote period of lake-dwellers who perched their habitations on props driven into the beds of lakes. Yet, however ancient in origin, piling continues in vogue at the present day as one of the most serviceable methods of providing underground or subaqueous support for structures. At the same time, it is a branch of engineering which admits of considerable diversity of practice and opinion. Piles

are varied in character, and formulæ for driving them are numerous, with results that are oftentimes conflicting. A handbook, therefore, which brings together, for comparison, data relating to the varied forms taken by piles and the rules governing their use is a useful *vade mecum* for the engineer.

The author has covered the ground very fairly, and though in some directions, perhaps, his survey might have been amplified with advantage, yet, on the whole, it is reasonably comprehensive. It covers a brief description of timber piles, with notes on their durability and treatment, and then, at greater length, deals with the numerous varieties of reinforced concrete and steel piles, both for bearing and sheeting. There are chapters on pile-driving and the handling of disc and screw piles, followed by an informative section on the theoretical carrying capacity of piles and the stability of walls and cofferdams, in which the mathematical treatment of the subject is well set out. The book concludes with several tabular appendixes and an index. It is well printed, and the illustrations and diagrams are clear.

B. C.

Theory of Alternating Current Wave-Forms

By Philip Kemp. (A Series of Monographs on Electrical Engineering, Vol. 1.) Pp. ix+218. (London: Chapman and Hall, Ltd., 1934.) 15*s*. net.

THE invention of the oscillograph enabled electrical engineers to gain a further insight into many curious electrical phenomena. Some of these had been investigated mathematically previously, and in most cases the instrument gave a complete verification of the mathematical theory. The author begins by explaining how a periodic wave can be resolved into its harmonics. He then gives many useful mathematical theorems. He proves, for example, the conditions that the current and voltage waves must fulfil in order that the average power expended may equal the product of the effective volts by the effective amperes.

Several methods are given for harmonic analysis. Some of them assume that the function can be expanded in a finite number of sine and cosine terms having frequencies in the ratio of 1, 2, 3, etc. In fact, they give a method of interpolation that was used by Clairaut and Lagrange seventy years before Fourier published his theorem. We doubt whether it is possible to compute the amplitude of the 25th harmonic when the half base is divided into only twenty-six parts and the ordinates measured. Using Lagrange's solution and applying it to a rectangular wave, we find that the computed value of the amplitude of the eleventh ordinate when the half base is divided into twelve equal parts is only one fifth of the true value. Applying Hardy's rule directly to Fourier's solution in this case, the error in the amplitude of the eleventh harmonic found is less than three per cent. We think that by far the best and least laborious method of finding the amplitudes and the phases of the various harmonics is to apply some of the known methods of graphical integration to Fourier's solutions.

Problems in Electrical Engineering, with Answers

Edited by Prof. S. Parker Smith. Second edition, revised and enlarged. Pp. xiv+210. (London: Constable and Co., Ltd., 1935.) 5*s*. net.

A BOOK containing more than a thousand somewhat difficult problems, the answers to which are all given, represents a great deal of labour. It also shows that, to a first approximation, electrical engineering has become an exact science. This book will be a help to all teachers of electrical engineering, especially in their exercise classes. The students attempt the examples which have been set and the teacher goes round the class and helps them individually. The examples are suitable for a three years college or university course. As a guide to the students, the easier examples are marked with an asterisk. We congratulate the editor on having produced such a useful book.

Geography

The Fiord Region of East Greenland

By Louise A. Boyd, with Contributions by J. Harlen Bretz, O. M. Miller, Walter A. Wood, William B. Drew, Charles B. Hitchcock and John K. Wright. (American Geographical Society, Special Publication No. 18.) Pp. xii+369+14 plates. (New York: American Geographical Society, 1935.) 4 dollars.

MISS L. A. BOYD, with the help of the American Geographical Society, organised and led an expedition to the Franz Josef and King Oscar fjord regions of East Greenland in 1933. The primary object was the study of fjord formation. This composite volume gives the important results of the work.

After Miss Boyd's narrative, with much good descriptive work, comes a study of the origin of the fjords by Prof. J. H. Bretz. He finds them to be stream-eroded valleys modified by glacial action, and in only one valley does he find clear evidence of fault action. Post-glacial frost action is very marked but not more on the coast than elsewhere, which possibly may be explained by the constant rising of the land. There is no strand flat in Greenland, but nevertheless Prof. Bretz believes that Nansen's theory of the strand flat formation by the product of wave action and frost action receives some support from Greenland.

The volume contains several new maps, many oceanographical data and a large collection of superb illustrations. A chapter on the botany of the region, as well as Jan Mayen, is important. R. N. R. B.

World Sugar Production and Consumption: an Economic-Geographical Survey

By Dr. C. J. Robertson. Pp. vii+142. (London: John Bale, Sons and Danielsson, Ltd., 1934.) 5*s*. net.

DR. ROBERTSON'S present association with the International Institute of Agriculture at Rome has ensured an adequate use of statistics in this book whilst his training in the University of London has given it a viewpoint which will render it of considerable value, as a convenient summary, to economists and geographers. After reviewing the general conditions of

cane and beet-sugar production, he treats each major producing area in turn, stressing the variations in unit-yields from one area to another. The huge expansion in consumption which is considered possible could largely be met by increasing the yields in Cuba (2–3 tons per acre) or India to those of Java which have risen from 1·1 to 6·5 tons in the last century. The Indian statistics cease with 1932–33, but the recent expansion is predicted. It is considered that if protection were removed, beet-sugar would practically disappear. L. D. S.

Europe: a Regional Geography

By Margaret Reid Shackleton. (University Geographical Series.) Pp. xvi+430. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1934.) 15*s.* net.

Behind the freshness of the writing and the sometimes almost casual treatment of a wide field there is evidence of extensive reading, a sympathetic understanding and not infrequently of an acute perception reminiscent of L. W. Lyde at his best. This is not a school book, nor is it an adequate university textbook, but it may be cordially recommended to all who have been accustomed to, and have perhaps tired of, the formal presentation of the facts of European geography and who seek a broader view in the understanding of current problems. Britain is excluded from consideration.

Mathematics

The Differential Calculus

By Theodore Chaundy. Pp. xiv+460. (Oxford: Clarendon Press; London: Oxford University Press, 1935.) 35*s.* net.

There has long been a need for a modern English textbook on the advanced parts of differential and integral calculus. The older books were comprehensive in scope, but deficient in rigour; the newer ones give a careful discussion of limits and continuity, but they ignore such topics as Jacobians and maxima and minima of functions of two independent variables. Many years ago, Mr. Chaundy started to write a differential calculus which should combine the English plan with Continental rigour, but in the course of time it has developed into something rather difficult to classify.

The book is intended to be a complete and self-contained treatment of the differential calculus so far as it concerns the real variable, excluding applications to geometry and mechanics. It would have been more convenient to students if the author had abandoned his attempt to be self-contained, an ideal not fully attained, as on p. 14 a rather difficult theorem on limits is quoted from Bromwich's "Infinite Series". The contents of Hardy's "Pure Mathematics" might reasonably have been assumed to be known to every student of higher mathematics; by taking this as a starting point, Mr. Chaundy could have made his book much shorter and cheaper.

There are fourteen chapters, dealing respectively with functional dependence, the continuous function (two), the derived function, higher derivatives, partial differentiation, indeterminate forms, analytic functions, maxima and minima (two), implicit functions, Jacobians and Hessians, differential operators, and expansions in power series. Many parts are of great interest, and some of these contain information difficult to find elsewhere. New terms are introduced, such as "vanishingly uniform convergence", and "umbral derivative", and there are several variations from the orthodox notation, some of which seem to be improvements. There are about four hundred carefully chosen examples, and a detailed index.

Lectures on Matrices

By J. H. M. Wedderburn. (American Mathematical Society Colloquium Publications, Vol. 17.) Pp. vii+200. (New York: American Mathematical Society; Cambridge: Bowes and Bowes, 1934.) 3 dollars.

The calculus of matrices has had a curious history. It was first used by Hamilton in 1853 under the name of "Linear and Vector Functions". Cayley used the term matrix in 1854, and developed the basic notions of the theory in 1858 without recognising the relation of his work to that of Hamilton. The algebra of matrices was rediscovered by Laguerre in 1867 and by Frobenius in 1878. Sylvester wrote a large number of papers on matrices, especially in the years 1882–84. After this, although the subject was never entirely dropped, it certainly seemed for many years to be regarded as of little interest to mathematicians in general. Then suddenly came a change. In 1925 Heisenberg's quantum mechanics created a widespread interest in matrices among physicists and applied mathematicians. It is significant that in the bibliography given at the end of the book under review, the average number of entries for 1853–1924 is 5·3 a year, rising to 18·3 for the years 1925–33, although the basis of selection has been narrowed for the later years.

Dr. Wedderburn's book is founded on lectures given at Princeton University at various times since 1920. It contains ten chapters, dealing respectively with matrices and vectors, the characteristic equation, invariant factors, vector polynomials, compound matrices, Hermitian matrices, commutative matrices, functions of matrices, automorphic transformations, and linear associative algebras. The subject is treated from the point of view of pure mathematics, without any explicit reference to physics, but some of the topics may easily be recognised as those which are of great importance in quantum mechanics.

Generalized Hypergeometric Series

By Dr. W. N. Bailey. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 32.) Pp. vi+108. (Cambridge: At the University Press, 1935.) 6*s.* 6*d.* net.

The ordinary hypergeometric series, discussed by Gauss about a century ago, is well known; it is a function of three parameters, of which two occur in the numerator and one in the denominator. In the

generalised series, the number of the parameters in the numerator and denominator may be anything we please. Until comparatively recently, it was difficult to obtain anything like a complete grasp of the scattered work on these series. Cayley, in 1858, published, without proof, a theorem which he had inferred from considerations of planetary theory, and it was not until forty-one years later that a proof was discovered (by W. McF. Orr). Ramanujan rediscovered for himself many results already known but not accessible to him. The first systematic account of the subject was contained in Hardy's paper, "A Chapter from Ramanujan's Note-book" (1923). Since then numerous papers have been published, and at the suggestion of Prof. L. J. Mordell this tract, dealing largely with recent work, has been prepared by Dr. Bailey, who has himself played a leading part in the development of the subject.

At a meeting of the Mathematical Association some years ago a speaker introduced the terms 'purist' and 'fusionist'. Dr. Bailey is evidently a purist, who keeps to the straight and narrow path of his subject, and sternly resists the temptation to stray into attractive cross-roads. As the preface points out, "all parts of the subject, such as asymptotic expansions, which definitely belong to function theory, have been deliberately ignored". It is difficult for a reviewer with fusionist prejudices to approve of this policy, but in all other respects the tract may be commended. H. T. H. P.

Miscellany

The Subject Index to Periodicals, 1934

Issued by the Library Association. Pp. xii+283. (London: The Library Association, 1935.) 70*s*.

THE editor, Mr. Rowland Powel, and his voluntary contributors, are to be congratulated on having succeeded in publishing this subject index to the contents of periodicals that appeared in 1934 some six weeks earlier than was the case with the corresponding volume last year.

The entries in the index are taken from 539 English and American, 26 French and Belgian, 21 German and 2 Italian periodicals. In the list of periodicals indexed, fuller bibliographical information is now given, including name and address of the publishers, frequency of publication and price (where possible). It is hoped that these details will enable those who make use of this subject index to procure a copy of any particular paper they may wish to possess.

Since last year, the selection of French and German periodicals indexed has been carefully revised, with the object of making the list more useful and comprehensive.

With few exceptions, no attempt has been made to index periodicals covered by the following publications: *Agricultural Index*, *Engineering Abstracts*, *Engineering Index*, *Index Medicus*, *Journal of the Society of Dyers and Colorists*, *Photographic Abstracts*, *Revue de Géologie*, *Royal Meteorological Society*, *Science Abstracts*, *Textile Institute Journal*.

The fact that this is the ninth year of the publication of this subject index in its present form is evidence that the index is widely recognised as an aid in the difficult process of finding what has already been published on any particular subject. We hope, indeed, that the Library Association will make this index a permanent feature of its activities.

Fifty Years in Public Health:

a Personal Narrative with Comments. By Sir Arthur Newsholme. Pp. 415+11 plates. (London: George Allen and Unwin, Ltd., 1935.) 15*s*. net.

IN this volume, Sir Arthur Newsholme records his recollections, mainly limited to occurrences bearing on public health, from childhood down to the year 1908, when he was appointed to the Local Government Board, as it then was. This period, covering the time when he was in general practice and later medical officer of health of Brighton, was one of great development in preventive medicine, for it witnessed the growth of the science of bacteriology from the beginning, the institution of important administrative measures in public health, and profound changes in epidemiological theory.

Sir Arthur Newsholme's birthplace and home for many years was the village of Haworth, where the Brontës lived, and of whom he has some stories to tell, for some of his friends had known them, and his father had been the Rev. Patrick Brontë's churchwarden. In his student days at St. Thomas's Hospital, he came under the spell of John Syer Bristowe and Charles Murchison, notable physicians of the period, and was an onlooker on Ord's clinical researches upon myxœdema. Sir Arthur was also a spectator of the introduction of antiseptic surgery, and had the opportunity of contrasting surgical work carried out on old-fashioned lines with Listerian methods; altogether, his student days happened at a vital transition period of medical practice.

Some of the pioneers in State medicine are next considered—John Simon, Edwin Chadwick, William Farr, Benjamin Ward Richardson and others—and an outline of their work is given. Further on, we find illuminating chapters on the prevention of milk epidemics, and the control of diphtheria, typhoid fever and tuberculosis, and this interesting and inspiring volume concludes with remarks on the care of infancy and childhood, and the control of some of the diseases of the young. The book is illustrated with a number of charts, and with plates of the outstanding figures in preventive medicine of the period. R. T. H.

This English

By Sir Richard Paget. Pp. xii+118. (London: Kegan Paul and Co., Ltd., 1935.) 4*s*. 6*d*. net.

"GENETIC, as distinguished from a purely historical, philology," says Dr. Marett in his preface to this book, "can never hope to verify its guesses." Yet, as he goes on to add that Sir Richard Paget at the close of a lecture at Oxford was successful in identifying the meaning of fifty per cent of Chinese words in a test, it is evident that if his theory of the origin of language cannot be proved, it has some measure of experimental support, resting on a basis more

substantial than that subjective conviction, which is the best, as a rule, that most theories on this subject can produce.

During the last ten years, Sir Richard Paget has been engaged in elaborating a theory of the origin of language, and in collecting evidence from a wide variety of languages in support of his view that the movements of the tongue in producing certain sounds determine the meaning of the words they compose. To put it rather differently, the movements of the tongue are a variety of the sign language once widely used between primitive peoples and still, or at least until recently, surviving among, for example, the Indians of America. In this book, this principle is applied in some detail to the sounds of spoken English. One example will suffice. The sound *Sp*, corresponding with the motions of mouth and tongue in making it, expresses the meaning of a fine point as in 'spear', 'spin', 'asp' or 'wasp'.

It may be doubted how much of the author's interpretation is subjective, notwithstanding his many striking examples. This feeling grows when it is found that such terms as 'wellington' (boot), 'kit-kat' (picture) and others of a like derivation are found to fall in with the author's theories. He would explain them as a species of philological survival of the fittest.

Philosophy and Psychology

On Dreams

By William Archer. Edited by Theodore Besterman. Pp. xv+215. (London: Methuen and Co., Ltd., 1935.) 7*s*. 6*d*. net.

William Archer is best known to us as a very loyal disciple of Henrik Ibsen and the editor of the English edition of his plays. It is therefore interesting to hear his views on dreams. He is not a disciple of Freud—indeed he thoroughly disagrees with a great deal of Freudian doctrine. It is, however, often difficult to accept Freud without being analysed.

To say that Freud is "misled by three influences; first, by a love of sweeping statements, with its correlative hatred of exceptions and reservations; secondly by a very natural tendency to forget that the great mass of his evidence is gathered from more or less brainsick people; thirdly, by an unfortunate obsession, which might very properly be made the subject of study by his own methods" is, we feel, not at all an accurate criticism. We have no evidence that Freud suffers from an obsessional neurosis; if he did, he would have been analysed and cured of it while Archer was still a young man.

The author gives us, among others, chapters dealing with visions and dreams, wish fulfilment, moral sense in dreams, sources of dreams and physically stimulated dreams. He then provides us with more than sixty dreams of his own which are very interesting. Throughout the book we are constantly reminded of the fact that for a layman, however erudite, to attempt to solve psychological problems without years of training in normal and abnormal psychology is little short of sheer waste of time.

God and Creation: God, a Cosmic Philosophy of Religion

By Prof. John Elof Boodin. Pp. 240. 8*s*. 6*d*. net.

God and Creation: Three Interpretations of the Universe

By Prof. John Elof Boodin. Pp. 519. 12*s*. 6*d*. net. (New York: The Macmillan Co., 1934.)

With these two volumes, Prof. Boodin's world-philosophy takes shape definitely. His idealism, which has a strong taste of pragmatism in his earlier works, asserts itself more and more in the traditional vein inspired by Plato. The "Three Interpretations of the Universe" is a learned treatise of critical cosmology, while 'God' makes a more direct appeal to reason and the heart, in favour of a comprehensive idealist view of the universe and of Deity. In both works, Prof. Boodin shows a great earnestness of purpose, the more so as he believes that Protestantism will go on decaying theologically, unless it establishes its national foundations on the solid ground of an idealist philosophy. Even one who does not share the philosophical beliefs of the author has to acknowledge with satisfaction the masterly contribution of Prof. Boodin to the solutions of the higher riddles of the universe. T. G.

L'Année psychologique

Publiée par Prof. Henri Piéron. (Bibliothèque de philosophie contemporaine.) Année 34 (1933). Vol. 1. Pp. xxvii+432. Vol. 2. Pp. 433–1167. (Paris: Félix Alcan, 1934.) 120 francs.

We can do no more than bring to the notice of our readers this important annual publication, which gives a short but most helpful summary of all the works and memoirs on psychology published during the preceding year. The first volume contains also nine original memoirs on various problems of experimental psychology by H. Piéron, R. H. Gault, M. Foucault, C. Durup, R. Dellaert, P. Kucharski, A. Zaganczyk, S. Korngold and A. Lévy.

Physics

The Diffraction of Light, X-Rays and Material Particles:

an Introductory Treatment. By Prof. Charles F. Meyer. Pp. xiv+473. (Chicago: University of Chicago Press; London: Cambridge University Press, 1934.) 22*s*. 6*d*. net.

A proper understanding of the principles of diffraction has never been so important to the student of physics as it is at the present time, and, with this in mind, Prof. C. F. Meyer has written a useful introductory work. That portion of the book which deals with the diffraction of light is indeed an excellent example of the treatment of problems in wave optics by the graphical method of the phase-amplitude diagram. Prof. Meyer uses this elegant geometrical method almost exclusively, and succeeds in giving a very lucid, and, within the limits of the method, which in his skilful hands are wide, a very detailed account of the various types of diffraction phenomena.

The sections on the rectilinear propagation of light, and on the Fresnel and Fraunhofer diffraction phenomena follow lines which are on the whole familiar, but they gain greatly from the many excellent diagrams with which they are illustrated. Enough distinction is not, however, made between the diffraction curves giving intensity and amplitude. In several cases, for example in Fig. 83, the amplitude curve is shown as having minima of zero slope at the points of zero amplitude. The slope is as a matter of fact a maximum at these points, and the curve should strictly cross the axis.

About eighty pages are devoted to the diffraction grating, and this section contains much matter, particularly that dealing with the theory of errors of ruling, and of optical ghosts, which has not hitherto been available in a textbook.

One cannot help feeling that in the sections of the book dealing with the diffraction of X-rays and of electrons by crystals the author is less at home than he is with purely optical problems. The treatment so far as it goes is adequate, but the emphasis is not always that which a worker in the subject would have given, and opportunities for bringing out the analogies with optical problems seem sometimes to have been missed. The book, however, can with confidence be recommended to students of optics.

R. W. J.

A Treatise on Hydromechanics

Part 2: Hydrodynamics. By A. S. Ramsey. Fourth edition. Pp. xii+415. (London: G. Bell and Sons, Ltd., 1935.) 16*s*. net.

THE influence of aeronautics on the academic hydrodynamics of a 'classical fluid' shows itself in this fourth edition of Part 2 of Ramsey's "Hydromechanics". Thus a chapter on viscosity has been added, as well as a discussion on the relation between circulation and lift of an aerofoil. There is given also some of the work due to Prandtl, Joukowski, Glauert, Jeffreys and others. Although the use of vectors or tensors has been considered and rejected, it might have been wise to follow the example of Maxwell, who in his famous treatise on "Electricity" long ago stated his results in vector form so as to give a clearer physical picture of his mathematical formulæ.

Technology

Principles of Phase Diagrams

By J. S. Marsh. (Alloys of Iron Research, Monograph Series.) (Published for the Engineering Foundation.) Pp. xv+193. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 18*s*. net.

THE application of the phase rule to metallic systems sometimes presents difficulties, which, however, would be avoided if the principles laid down by Gibbs were strictly adhered to. A lax interpretation has become common, and it has been thought advisable to include, in a series of books devoted to the technical properties of the alloys of iron, an account of the principles on which phase diagrams are constructed and interpreted. The author has followed Gibbs throughout, and has kept to a strictly thermodynamical treatment, ignoring all questions of atomic arrangement.

The work has been done thoroughly, and the author is at pains to be logical, even at the cost of making some of the chapters rather hard reading for the metallurgist. It is only at the end of the book that any concrete examples are given, and then the ternary system selected, that of iron-carbon-silicon, is an unfortunate one, having been very inadequately studied in the laboratory. The terminology of much writing on metallic phase diagrams being rather loose, the author has suggested one on strictly logical principles. No objection can be taken to it on this ground, but the number of new terms is so large as to make it unlikely that it will be widely adopted. A simpler treatment would have been more helpful, but a careful study of this book will repay itself. In the modern study of alloys, however, changes which can only be accounted for by movements of atoms fall to be considered, such as the ordered-disordered changes in solid solutions and the precipitation of ultra-microscopic particles in age-hardening, and it would be of interest to discuss how far these can be represented in any system of phases.

Liquid Fuels:

their Manufacture, Properties, Utilisation and Analysis; a Practical Treatise for Engineers and Chemists. By Harold Moore. Pp. viii+264+4 plates. (London: The Technical Press, Ltd., 1935.) 21*s*. net.

THE book is put forward as a manual for chemists and engineers interested, but not specialists, in the subject of liquid fuels. Mineral oils, shale, tar oil, benzole, alcohol and vegetable oils and their manufacture are briefly described. Their behaviour, singly and admixed, in internal combustion engines is treated in considerable detail, both for engines with spark and compression ignition. Then follows the preparation and use of heavier oils for external combustion, including domestic heating and lighting. The value of the section on analysis and testing is increased by the author's comments on the significance of results of the various tests.

On the technology of coal products, the book is less precise. The author does not indicate the rapid growth of benzole production by gas works now in progress. Indeed, he seems to imply that the practice ceased after the War. On p. 49 he states that the horizontal gas retort tar is the "main source of benzene". Although the 'inhibitor' process is revolutionising the refining of benzole, it does not appear in the index. 'Gas oil' is an important fraction of petroleum, but no indication is given of the requirements of a good oil for carburetting water gas, and its use for this purpose would appear to be subsidiary to that of domestic fuel.

Leaving aside such criticisms, there must be many users and potential users of liquid fuels who need the information in this book, and to them it may be heartily commended.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

Apparatewesen E.V., held at Königsberg on July 3–5 last, indicate that the object aimed at is the use of raw materials obtained in Germany in the manufacture of German goods. When a suitable material, native to that country, is not available, steps should be taken to enable other materials, found in Germany, to be adapted for the required purpose. Where, however, suitable substitutes cannot be found, investigations should be made with the view of constructing the plant or article using the minimum quantities of imported materials. No details regarding how these objects are to be attained are given, so that unless the original papers are studied, little more than an outline of the subjects considered can be obtained, the motto of the congress being "Nur deutsche Stoffe für deutsche Waren".

Engineers' Study Group on Economics

THE Engineers' Study Group on Economics is entering its third year of activity, and Sir Richard Gregory has been elected president for the year. The Group consists of six sections investigating the various factors that may help to solve the present paradox of poverty amidst plenty. An analysis of twenty-four existing or proposed social and economic systems, prepared by Section B of the Group, was noticed in NATURE of May 25, 1935, p. 884. Section A, which is investigating the available, the desirable and the potential production of Great Britain, hopes to present a similar report shortly. Scientific workers, not necessarily engineers, willing to help in the application of scientific principles to the urgent problems of the day are welcomed by the Group. The yearly subscription is: minimum 5*s*., maximum £1. Sections meet in the evening at 85 Gloucester Place, W.1. The next group meeting will be at the Guildhouse, Eccleston Square, S.W.1 (Berwick Street entrance), on Tuesday, October 15, at 7 p.m.; Sir Richard Paget will speak on his recent visit to the U.S.S.R. Those wishing to attend should notify the honorary secretary, A. H. Hayes, Hazlitt House, Southampton Buildings, W.C.2 (Tel.: Holborn 1068).

Tsetse Fly Control

THE report of the East Africa Sub-Committee of the Tsetse Fly Committee, Economic Advisory Council (Cmd. 4951. London: H.M. Stationery Office. 1*s*. net), epitomises many factors bearing upon the problems of human sleeping sickness, as well as of tsetse fly diseases of animals, in Africa. Both diseases are caused by trypanosome parasites and are transmitted by tsetse flies, so that methods for eradication of the flies constitute important preventive measures. The most recent advance in this direction is by means of densification of the vegetation. It has been found that if a patch of tsetse-infested bush is protected from grass fires for several seasons, the growth becomes so dense as to be highly unfavourable to certain species of tsetse, and further investigation on these lines on a large scale is desirable.

Therapeutic Substances

THE Joint Committee constituted under the Therapeutic Substances Act, 1925, has issued additional regulations dealing with several agents, namely, staphylococcus toxoid, antipneumococcus serums (Types i and ii), staphylococcus antitoxin, gas-gangrene antitoxins and diphtheria prophylactic ("Statutory Rules and Orders 1935, No. 580"). The provisions applicable to these substances, which have now attained definite value in medical practice, include definition and proper name, labelling, quality, strength, and tests of potency, and unit of standardisation.

Export of British Scientific Instruments to France

CERTAIN kinds of British optical and scientific instruments are subject to special quotas when imported into France. In order to ensure the full benefit of these quotas to British manufacturers, and to prevent the detention of shipments, the French Government has authorised the Scientific Instrument Manufacturers Association of Great Britain to issue certificates to shippers. The instruments to which these certificates apply are as follows:—simple surveying instruments; dividing machines; house barometers; apparatus for physical and chemical demonstration for schools and colleges; apparatus for physical and chemical researches and analyses; surveying instruments for geodesy, topography and measurements of angle. More precise information may be obtained from the Secretary, Scientific Instrument Manufacturers Association of Great Britain, Limited, 329 High Holborn, London, W.C.1.

International Exhibition of Nature Photography

THE Right Hon. the Earl of Onslow, president of the Society for the Preservation of the Fauna of the Empire, will open an International Exhibition of Nature Photography in the Whale Hall of the British Museum (Natural History), South Kensington, on Wednesday, October 16, at 12 noon. The object of the exhibition is to show the advance nature photography has made during recent years; and the exhibition should be of considerable interest and educational value. It will remain open every day from 10 a.m. until 6 p.m. (Sundays 2.30 p.m. until 6 p.m.) from October 16 to November 30. Admission is free. More than 1,200 photographs of birds and mammals will be shown, including examples from all British Colonies as well as from the United States, Poland, Japan, etc.

French Congress of Hygiene

THE twenty-second French Congress of Hygiene will be held at the Institut Pasteur, Paris, on October 21–23, when the chief subjects for discussion will be the hygiene and protection of infancy, and will be followed on October 23 by a meeting of the Société de la météorologie médicale, an offshoot of the Société de médecine publique. Further information can be obtained from the general secretary, Dr. Dujarric de la Rivière, Institut Pasteur, rue Dutot, Paris.

German Pharmacological Society

THE German Pharmacological Society will hold its annual meeting at Munich on October 20–23, when

the following subjects will be discussed: (1) water excretion of mammals and its physiological regulation, introduced by Verney of Cambridge; (2) the problem of the relation between chemical constitution and pharmacological therapeutic action, introduced by Schuleman of Elberfeld; (3) hynotics and basal narcosis, introduced by Weese of Elberfeld, Schön of Leipzig and Frey of Düsseldorf; (4) pharmacology and clinical employment of circulatory stimulants, introduced by Hildebrandt of Giessen and Killian of Freiburg. Further information can be obtained from Prof. Janssen, Pharmacologisches Institut, Freiburg i. B., or the general secretary, Prof. B. Behrens, Dorotheenstrasse 28, Berlin.

Announcements

THE RIGHT HON. J. RAMSAY MACDONALD will open the Coal Hydrogenation Petrol Plant of Imperial Chemical Industries, Ltd., at Billingham-on-Tees, Durham, on October 15.

AN *Exchange* telegram from Copenhagen states that Prof. Niels Bohr, on his fiftieth birthday on October 7, was handed 100,000 kroner (nearly £4,000), which has been subscribed for among scientific societies in Denmark for the purchase of radium for research.

THE following appointments have recently been made by the Secretary of State for the Colonies: Mr. A. Pickles, to be entomologist, Department of Agriculture, Trinidad; Mr. J. W. Costello, late assistant conservator of forests, to be assistant conservator of forests, Nigeria; Mr. T. A. Strong, deputy conservator of forests, to be conservator of forests, Malaya; Mr. J. G. Watson, conservator of forests, to be deputy director of forests, Malaya.

A BIOCLIMATIC investigation department is to be established at Bad Pyrmont under the direction of Reg. Rat Lossnitzer, of Berlin.

AN institute for the biology of heredity and racial hygiene has been opened at Frankfurt-on-Main under the direction of Prof. Eugen Fischer.

THE King of the Belgians has recently laid the first stone of a cancer institute bearing the name of Jules Bordet, in honour of the former director of the Pasteur Institute of Brussels. The Institute is attached to the new Hôpital St. Pierre, Brussels.

A POWER Farming Conference will be held in Oxford in January next under the auspices of the School of Rural Economy, the Institute for Research in Agricultural Engineering, and the Agricultural Economics Research Institute. The date provisionally fixed for the Conference is January 7–10.

DURING the recent International Congress of the History of Medicine at Madrid, the degree of doctor *honoris causa* was conferred at the ancient University of Alcala en Henares among others on Sir Humphry Rolleston, the British delegate, and Profs. Neuburger of Vienna, Diepgen of Berlin, Laignel-Lavastine of Paris and Sigerist of Johns Hopkins, who occupy the chair of the history of medicine in their respective universities.

BY courtesy of the Compagnie Générale Transatlantique, the Science Museum, South Kensington, has secured the loan of a fine model, more than ten feet in length, of the *Normandie*, the present holder of the Blue Riband of the Atlantic. The *Normandie* has a length of 1,029 ft., beam 119 ft., tonnage 79,280, and turbo-electric machinery developing 160,000 horse-power. Her record-breaking run, New York to Plymouth, was accomplished in 4 days 3 hr. 25 min. at an average speed of 30·31 knots.

MESSRS. A. GALLENKAMP AND CO., LTD. (Technico House, Finsbury Square, London, E.C.2), have issued a revised edition of their catalogue "Apparatus for the Examination of Soil". The list includes the latest patterns and modifications of standard apparatus used in connexion with all types of soil work. Where desirable, directions for use are included, together with the appropriate bibliographical references, so that direct contact with the scientific origin of the apparatus is possible.

ERRATUM.—In Prof. Karl Pearson's letter on "Statistical Tests" in NATURE of October 5, p. 550, the values of the eccentricities e should have been given in tenths, not hundredths; that is, $e = 0{\cdot}6$, not $0{\cdot}06$. This has no bearing on the argument.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A research assistant in insect physiology in the Imperial College of Science, South Kensington, S.W.7 (Oct. 15).

A lecturer in mechanical engineering in the Birmingham Central Technical College—The Principal (Oct. 19).

A chemist in the Admiralty Chemical Pool—The Secretary of the Admiralty (C.E. Branch), Whitehall, London, S.W.1 (Oct. 25).

A junior assistant for the Directorate of Explosives Research—The Chief Superintendent, Research Department, Royal Arsenal, Woolwich, S.E.18 (Oct. 26).

A lecturer in mathematics in Goldsmiths' College—The Warden, Goldsmiths' College, New Cross, S.E.14 (Oct. 28).

A lecturer in physics in the University of Cape Town—The Secretary to the High Commissioner for the Union of South Africa, Trafalgar Square, London, W.C.2 (Nov. 5).

A virus physiologist at Rothamsted Experimental Station, Harpenden, Herts—The Secretary (Dec. 15).

An assistant lecturer in agriculture in the Midland Agricultural College, Sutton Bonnington, Loughborough—The Principal.

the following subjects will be discussed: (1) water excretion of mammals and its physiological regulation, introduced by Verney of Cambridge; (2) the problem of the relation between chemical constitution and pharmacological therapeutic action, introduced by Schuleman of Elberfeld; (3) hynotics and basal narcosis, introduced by Weese of Elberfeld, Schön of Leipzig and Frey of Düsseldorf; (4) pharmacology and clinical employment of circulatory stimulants, introduced by Hildebrandt of Giessen and Killian of Freiburg. Further information can be obtained from Prof. Janssen, Pharmacologisches Institut, Freiburg i. B., or the general secretary, Prof. B. Behrens, Dorotheenstrasse 28, Berlin.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 609.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Robert Hooke and his Contemporaries

SOME among us, long interested in the life and times of distinguished scientific and literary personaliti of the mid-seventeenth century, would fain ret the opinion that Henry Oldenburg was eminentl ..tted to occupy the special post that was assigned him; moreover, that his very detachment from the realms of experimental adventure and inventiveness actually facilitated and did not invalidate remarkable services, securing freedom, with a responsibility of high order.

Yet we find the reviewer of "The Diary of Robert Hooke" (NATURE, Sept. 7, p. 358) writing as follows: "I, for one, have the impression that he [Oldenburg] was an oblique, intriguing and toadying individual, jealous of Hooke's fame and earnings" (p. 360).

As a possible antidote to the implications of this conclusion, it is opportune to refer readers of NATURE to an article on Henry Oldenburg which appeared in this journal forty-two years ago (November 2, 1893), the author of which had an immediate and close intimacy with relevant documents, though not, it is true, with the lavender entries of an unpublished diary.

It may be found perhaps, on reference thereto, that the epithets "oblique" and "toadying" applied to Oldenburg cannot be sustained except at some sacrifice of historical propriety and appropriate justice.

The circumstance that no portrait of Hooke is extant is probably associated with his fickle physical condition. Certainly, he would have been a most difficult, wayward 'sitter'. We may, however, believe that Evelyn was sorry that Hooke did not occupy a place in that gallery of celebrities in which he himself was so interested. T. E. JAMES.

59, Sharp's Lane,
Ruislip.

IN his account of the extraordinarily intriguing, human and intimate part of the "Diary of Robert Hooke", published in NATURE of September 7, Prof. Andrade has suggested that the biographer, Richard Waller, "apparently had little personal knowledge of Hooke or his intimates". This may have been the case during the earlier period before 1680, but entries in the later Diaries, which I have recently transcribed and printed, show that Waller and Hooke were fellow members of a coffee-house coterie, that met almost daily at Jonathan's. It was the habit of Hooke to abbreviate the names of his friends, and many were the talks and walks in which Hooke mentions the companionship of "Lod", "Cur", or "Wall", either into the country or to attend book-auctions held in the vicinity. That no official portrait of Hooke was painted for the Royal Society, and that no obituary notice appeared of him in the *Philosophical Transactions*, may be ascribed to the fact that his death was immediately followed by the election of Newton to the presidential chair, and Newton is known to have been unfavourably inclined towards Hooke. The neglect was in part remedied when Waller printed the "Posthumous Works" of Robert Hooke in 1705.

R. T. GUNTHER.

The Old Ashmolean,
Oxford.
Sept. 17.

MR. JAMES'S letter is of interest as recording that he personally does not agree with my opinion of the character and temperament of Oldenburg, but it has little objective content. In my article I referred briefly to some of the facts on which I base my conclusions: the affair of the watch, where Oldenburg, who had a (secret ?) financial interest in a rival invention, went out of his way to decry Hooke's achievements, and certainly went beyond what he would have known: the undoubted political, although no doubt innocent, correspondence with foreigners, which he denied: the opinion of Sydenham. I may further point out that in his correspondence with Spinoza, extending over the years 1661–76, in which the scientific discoveries of the day are freely discussed, and the names of Boyle and Huygens occur again and again, there is only one reference to Hooke's work (to the "Micrographia", without mention of Hooke's name).

As for the question of jealousy, I am by no means alone in my opinion. To quote but one authority, Prof. More in his recent "Isaac Newton" says, *à propos* of Oldenburg's mischief-making between Newton and Hooke, "The motive for the advice [to Newton] may have been a sincere interest in his friend's welfare, but it was undoubtedly influenced by the evident jealousy which existed between himself and Hooke. As a consequence of his own antipathy, he exaggerated the Curator's [Hooke's] irascibility and gave the impression that matters were worse than they actually were. This time he succeeded." Elsewhere Prof. More has occasion to animadvert on reprehensible activities of Oldenburg.

If Mr. James would show that the points to which I have briefly referred cannot support my view of Oldenburg's character, and would state that there is nothing in the letters to Boyle which can be called toadyism, it would be more to the point than a vague and somewhat offensive insinuation that I have sacrificed historical propriety, and it would then be worth while for me to adduce other support.

The reference to the old article in NATURE (November 2, 1893) is curious. This article was unknown to

me, but on the other hand I am very familiar with the article in the "Dictionary of National Biography", which is from the same hand—that of Mr. Herbert Rix. The latter article, which cites Oldenburg's "peculiar temper", and his draft petition for a patent for Huygens' watch, has contributed to form my unfavourable opinion of Oldenburg's character. It further points out that Oldenburg first enthusiastically urged Spinoza to publish his writings, and afterwards withdrew. I have now read the NATURE article, and do not find that it runs counter to my views. Rix calls Oldenburg "an interesting man who lived in a most interesting period", and opines that without his endeavours, and those of Hooke, the Society would scarcely have held together, with all of which Mr. James and I will both agree. So far as I can see, there is nothing that shows any particular sympathy with Oldenburg's personal character, and Mr. Rix's other article, which was published two years later, and must represent his considered opinion, seems to me definitely unfavourable.

Hooke's character was manifestly imperfect, but he had the excuses of genius and chronic illness, neither of which can be advanced for Oldenburg. I was concerned not so much to estimate Oldenburg, who was, after all, a very second-rate intellect ("His scientific observations were certainly very mixed, many of them trivial, and some of them superstitious," says Mr. Rix), but rather to point out that Hooke had just cause to complain of him. I agree with Prof. More, where he refers to Hooke "showing the contrast of an essentially noble character in large matters with an irritable, suspicious and cynical temperament in the familiar affairs of life", and I am of the opinion that Oldenburg did much to embitter Hooke's character and to bring into prominence his weaker points. If all that can be done to shake my views as to Oldenburg's character is to refer to an article which stresses his undoubted industry and vast correspondence, and to sneer at Hooke's private record as "lavender entries", I shall continue in my error.

So far as I know, the Diary which Dr. Gunther has transcribed had not been published when I wrote the article in question. This alone is sufficient to account for my not having read it. I may add that Waller himself says "the greater part of my Vouchers have been either taken out of his own Memorials or from the Journals of the Royal Society", and although it is clear from his biography of Hooke that he had spoken with his subject on more than one occasion, there is nothing in it that bespeaks intimacy.

As regards the general question of a portrait, although none has survived, it seems probable from the Diary which I reviewed that one was made, for on October 16, 1674, we read "Mr. Bonust drew picture", and on December 24 of the same year, "The workmen left work did nothing but get together my picture frame". The painter, of whom it is earlier recorded "Mr. Janeway sat for picture to Mr. Bonus", was, according to Mr. Robinson's editorial note, probably Bownest, who painted portraits, principally of dissenting ministers. Perhaps, then, there is a portrait somewhere in existence.

The Meaning of Probability

I SUGGEST that Dr. Dingle's problem in his article in NATURE of September 14, p. 423, is not quite fairly stated. If Ohm's law has been found true in 9,999 cases and found false in one case, and if P who speaks truth once in 10,000 times says *he has found* it true, it is equally probable that he has struck the exceptional case and told the normal lie, or struck the normal case and told the exceptional truth. If this is not immediately clear, it becomes so on considering 10^8 experiments by P, assuming, as is proper, that the exceptional case occurs once in 10,000 times throughout. In this sense, the probability that P has found the law false is one half.

W. BARRETT.

Fuglestemmen,
Layters Way,
Gerrards Cross,
Bucks.
Sept. 16.

IN his article on 'The Meaning of Probability' in NATURE of September 14, Dr. Dingle has attempted to support his case by means of a striking example. Unfortunately his illustration is by no means happily chosen, and the issue may be further confused by his treatment of it in a way no one is likely to defend. When the truth (by which we do not mean the whole truth and nothing but the truth) of Ohm's law is in question, only evidence arising from experimental investigations is pertinent; no statement, independent of experimental work, by any individual, whatever his habit regarding the truth, is of value. On the data given, the probability that the law will be found to hold in a new experiment is therefore 9,999/10,000.

For the purpose of the discussion, Ohm's law must be replaced by a question in which individual testimony constitutes relevant evidence. If we then waive the debatable point of attaching any value whatever to the statement of so notoriously untruthful an individual, we cannot reach the probability $\frac{1}{2}$ put forward by Dr. Dingle. Each statement, like each experimental inquiry, has to be regarded as a separate item of evidence. In the absence of qualifying evidence, each is to be given equal weight. Dr. Dingle, on the other hand, invites us to regard the combined results of 10,000 experiments as no more than equal in weight to a single statement made by a confirmed liar. It is obvious that we exaggerate the effect of this statement on the probability if we replace it by an additional experiment unfavourable to the law. The probability, then, so far from falling from 9,999/10,000 to $\frac{1}{2}$, certainly does not fall as far as 9,999/10,001. The ratio which would result from the given figures by simple enumeration is, in a suitable problem, 9,999·0001/10,001.

It may be observed that the fractional part of the numerator would not become zero, even if the data were strengthened to the extent that the individual concerned had never been known to tell the truth.

T. SMITH.

National Physical Laboratory,
Teddington.
Sept. 17.

A SUFFICIENTLY general statement of the problem I was trying to exemplify is as follows:—*If we have two independent sources of information* (β *and* γ) *bearing on the question of the truth or falsehood of a proposition*

(α), *does a combination of* β *and* γ *make a significant contribution to the question?* My answer was, No; Dr. Sterne's was, Yes, because a combination could be found which would give a unique answer. I replied that uniqueness was not enough.

In the *A* and *D* problem and the Ohm's law problem, α, β and γ have the following meanings :—

	A and *D* Problem.	Ohm's Law Problem.
α	*D*'s remark is true	Ohm's law is true
β	*D*'s record	Experiment
γ	*A*'s weighted comment	*P*'s weighted comment

To me these two examples both come fairly within the general case. Mr. Barrett and Mr. Smith, however, appear to challenge this with regard to the second example. I will try to state their objections in terms of the general problem, and show why I believe them to be invalid.

Mr. Barrett's objection is, ultimately, that the two sources of information are not 'independent'. But that is only because he has arbitrarily assumed that *P*'s statement is based on one of the 10,000 experiments. *P*'s statement might have been groundless; he might have 'read about it in the papers' or, in fact, spoken on any ground whatever, *except* that which Mr. Barrett has assumed, for that makes his remark dependent on part of β.

Mr. Smith's objection is that γ is not 'information bearing on the question', because 'only evidence arising from experimental investigations is pertinent'. If he feels this, let him make the harmless supposition that *P* has performed an experiment in secret (outside the National Physical Laboratory, where the 10,000 experiments were made), and that his comment arises from this investigation. Mr. Smith's objection is then met. He will possibly retort that it is not met, because by 'experiment' he meant *experiment*, and not *P*'s report on experiment. If so, I would ask him whether he has personally verified every canonical fact in physics, or whether he has accepted some of those facts on hearsay. I think he must admit the latter alternative, not merely with regard to the statement of the results, but also with regard to the belief that those results were obtained by experiments, and were not invented. He can now dispense with the useless assumption that *P*'s statement is based on experiment, for since he cannot rule out a statement merely because it is hearsay, it makes no difference to his estimate of *P*'s statement, whether or not that statement includes an assertion that *P* has experimented.

I think, however, that what is at the *very* back of Mr. Smith's mind is that we must not allow the assertion of a convicted liar like *P* to affect our evaluation of statements of workers at the N.P.L. and other reputable institutions. In that I agree with him entirely: it is, in fact, just my argument against Dr. Sterne, who wishes to *combine* information from all sources, whereas I wish independent information to be kept independent.

I would summarise the attitudes of Mr. Smith, Dr. Sterne and myself (expressed, I think, rather than really intended, in the first case) to this question, as follows. Mr. Smith maintains that the two pieces of information are independent, but one of them is irrelevant, and he therefore rejects that one entirely. Dr. Sterne, while perhaps admitting that the pieces of information are independent, thinks that since they are both relevant, they can be combined into a unique, significant result. I hold that they are independent and both relevant, and therefore can yield two independent results the relative importance of which, of course, varies with the details of the problem.

If the foregoing analysis is valid, the last two-thirds of Mr. Smith's letter calls for no comment. I am puzzled, however, by his early casual remark that by truth "we do not mean the whole truth and nothing but the truth". I, at least, meant that. Perhaps he is merely asserting that, no matter how many experiments are performed, we do not necessarily *reach* the truth. That is so, of course, or we should not be talking about probabilities, but certainties. But I was assuming (without then or now committing myself to an opinion on this point, for fear of letting loose all the philosophers) what I imagined most readers of NATURE would agree about, namely, that the statement called 'Ohm's law' was true or false independently of our knowledge on the matter.

HERBERT DINGLE.

Imperial College,
London, S.W.7.
Sept. 20.

Negative Attenuation of Electromagnetic Waves and Sommerfeld's Theory of Ground Absorption

WE have recently measured the attenuation of wireless waves of 160 m. wave-length from a low-power Hartley transmitter installed in our laboratory. Measurements of electric field-strengths for various distances in two definite directions up to a distance of 4,800 m. have been carried out and the results are shown in Fig. 1. The attenuation factor *A* has been taken as the ratio $E.d./E_0.d_0$, where E_0 is the value of the field-strength at a distance d_0, which is so near the transmitter that there is no perceptible ground absorption and E is the value of the field-strength at any longer distance d. This ratio has been plotted as a function of the distance.

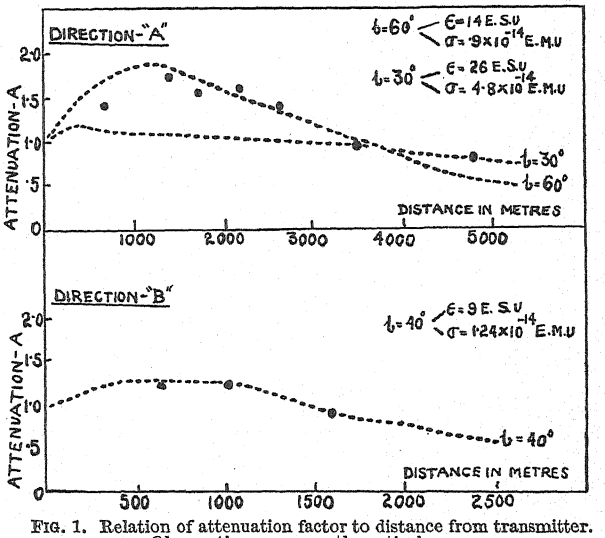

FIG. 1. Relation of attenuation factor to distance from transmitter. Observations, . . . ; theoretical curves, - - -

The results clearly indicate a negative attenuation of the wireless waves. In direction *A*, the attenuation at first rises to a value as high as 1·7 and then it gradually decreases and attains the value of unity at a distance of about 3,200 m. from the transmitter. The attenuation then falls below unity and gradually diminishes with distance in the usual way. In direction *B*, the attenuation rises at first to a value

of about 1·3, and then gradually falls and attains the value of unity at a distance of about 1,440 m. Beyond this, the value becomes less than unity and decreases gradually with the distance.

The negative attenuation, as has been pointed out by Ratcliffe and White[1], is to be expected under certain conditions from Sommerfeld's[2] theory of attenuation. According to Rolf[3], Sommerfeld's expression for attenuation can be represented in terms of only two quantities q and b when the field on the surface of the earth is considered. The quantities involve the electrical conductivity σ, the dielectric constant ε of the earth, the wave-length λ of the wireless wave, and the distance d from the transmitter.

Rolf has shown

$$\tan b = \frac{\varepsilon + 1}{6\lambda\sigma} \cdot 10^{-15} \text{ and } q = \frac{2\pi \sin b}{(\varepsilon+1)\lambda} \cdot d$$

where distances are expressed in kilometres, ε in E.S.U. and σ in E.M.U. The attenuation curves drawn by Rolf show that for certain values of b there is negative attenuation.

Making use of Rolf's graphs and Sommerfeld's formula in the form given by Rolf and comparing the theoretical values of attenuation with our observed values, we have been able to determine the values of b, ε and σ in the two directions for $\lambda = 160$ m. In direction A, we find that, up to about 3,500 m., there is agreement between theory and experiment for $b = 60°$, $\varepsilon = 14$ E.S.U. and $\sigma = 0{\cdot}9 \times 10^{-14}$ E.M.U. Beyond this, in the same direction towards the river side we require, $b = 30°$, $\varepsilon = 26$ E.S.U. and $\sigma = 4{\cdot}8 \times 10^{-14}$ E.M.U. for good agreement with Sommerfeld's theory. From the comparatively larger moisture-content of the soil, the lower value of b and the higher values of ε and σ are to be expected in this region. For direction B we have to put $b = 40°$, $\varepsilon = 9$ E.S.U. and $\sigma = 1{\cdot}24 \times 10^{-14}$ E.M.U. to suit Sommerfeld's theory. The theoretical curves are shown in Fig. 1 along with the experimental values of the attenuation. The observed value of attenuation at distance $d = 710$ m. in direction A is a little too low. This is attributed to the slight screening action of a brick wall.

The values of ε and σ obtained from the attenuation measurements for $\lambda = 160$ m. agree well with the values obtained by us for the different specimens of Dacca soil by the direct laboratory method.

It should be mentioned that the negative attenuation was first observed by Ratcliffe and Barnett[4] employing wireless waves of 1,600 m. wave-length from the Daventry Station of the B.B.C. Ratcliffe and Shaw[5] also observed the same thing with a shorter wave-length (30 m.).

Very recently, Norton[6] has pointed out an error in Rolf's calculations. Some calculations which we have made lead us to suppose that this error does not materially alter the attenuation curves given by Rolf, at least for *very short distances* from the transmitter.

Dissociation Energy of Carbon Monoxide and the Heat of Sublimation of Carbon

IN two letters, published in NATURE of June 29, P. Goldfinger, W. Lasareff and B. Rosen have calculated the heat of dissociation of carbon monoxide and afterwards the heat of sublimation of carbon. They obtain their figures from the predissociations of the term $B^1\Sigma$ and the number of observed vibrational levels of the term $A^1\Pi$ of CO. There is, however, still another possibility of determining $D_{(CO)}$ originally suggested by Kaplan[1]. Of each of the two electronic states $b^3\Sigma$ and b', only one vibrational level is known, and this leads to the assumption of a repulsive curve, intersecting the potential curves of these two levels at 10·6 v.e. This value is well between the lower and upper limits (10·4 and 11·07 v.e. respectively) calculated by Goldfinger and Lasareff, but slightly below their final estimated value of $11{\cdot}0 \pm 0{\cdot}1$ v.e.

The repulsive curve which intersects at 10·6 v.e. is then the *lowest* one of all those which involve the level $C(^3P) + O(^3P)$ of the separated system, and in an earlier publication[2] we have, therefore, taken the slightly lower value of 10·45 v.e. as that of $D_{(CO)}$ which leads to a value of 155·7 kcal./mol. for the heat of sublimation of carbon (β-graphite) at 25° C.

The value of 10·45 v.e. for $D_{(CO)}$ may be confirmed in the following way. The level $B^1\Sigma$ lies at 10·72 v.e.; linear extrapolation yields a value of its energy of dissociation of 2·94 v.e., which is not necessarily correct, but is certainly an upper limit of it. This value is based on the value of the enharmonic constant of 50 cm.$^{-1}$, which is not certain; it appears that this value is the lower limit for the enharmonic constant, the other possible value being 76 cm.$^{-1}$. Since this level cannot be correlated to the level $C(^3P) + O(^3P)$, and since it certainly involves a level of the separated system with equal multiplicity of the two atoms, it has to be correlated to the level $C(^1D) + O(^1D)$. The two energies of excitation of C and O are together 3·21 v.e., giving an upper limit of $D_{(CO)}$ of $10{\cdot}72 + 2{\cdot}94 - 3{\cdot}21 = 10{\cdot}45$ v.e.

Oxygen in the Sun's Chromosphere

PHOTOGRAPHS which I have taken at the Kodaikanal Observatory show that oxygen is a normal constituent of the sun's chromosphere, and is probably in great abundance.

Placing the slit of a spectrograph tangentially to the image of the sun's limb, I have found that the infra-red triplet of oxygen, λλ 7771, 7774 and 7775, shows as emission lines in the sun's chromosphere. This is not a unique appearance in one photograph only, for the reversal of the oxygen triplet into bright lines has been photographed every day since it was first observed.

Fig. 1 is a microphotometric record of one of my photographs taken on August 23, and clearly shows the oxygen lines as emission lines brighter than the continuous spectrum from the sky, compared with the neighbouring Fe and Ni absorption lines in the sky spectrum. When the chromosphere is not on

the slit, the sky spectrum, of course, shows the oxygen lines as absorption lines.

From the length of the emission lines as seen in my photographs with a straight slit tangential to the sun's limb, the greatest height reached by oxygen in the chromosphere is deduced to be 3·5″; but since the limb of the sun is probably a little distance from the slit at its nearest point (in order to avoid the risk of photospheric light entering the spectrograph) this is very likely an underestimate. In eclipse photographs, it is to be expected that the oxygen lines will extend to greater heights than this.

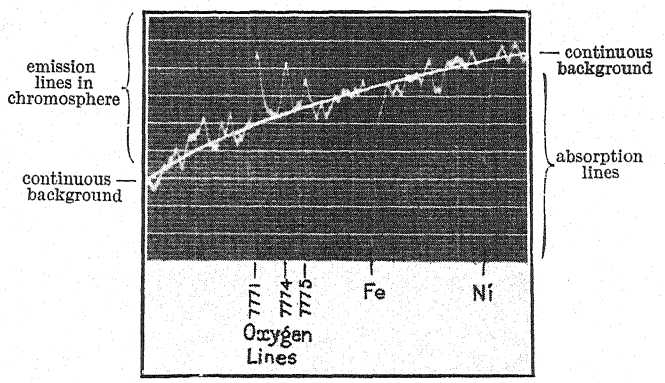

FIG. 1.

The presence of oxygen in the chromosphere, in addition to the previously known presence of H, He and Ca+, is of importance for the theory of support of the chromosphere. This question is more fully discussed, together with details of the observations, in *Kodaikanal Observatory Bulletin* No. 107 which will appear shortly.

Records of Fatalities from Falling Meteorites

WITH reference to the remark in NATURE of July 27, p. 128, in a notice of Prof. Heide's "Kleine Meteoritenkunde" that "it is reassuring to find that there is no certain evidence of any person having been killed by a falling meteorite", may I direct attention to the following:

(1) Humboldt in his "Cosmos", vol. 1 (English translation by E. C. Otté. London, Bohn, 1849, p. 124), writes: "Several persons had been struck dead by stones falling from heaven, as for instance, a monk at Crema on September 4, 1511; another monk at Milan in 1650 and two Swedish sailors on board-ship in 1674".

(2) T. L. Phipson, in his "Meteors, Aerolites and Falling Stars" (p. 85) (London: Lovell Reeve, 1867), also mentions these incidents and describes particularly the Crema incident at great length, as the result of a meteoric shower, citing "The Commentary" of Surius, a Carthusian monk of Cologne, "De Rerum Varietate" of Jerome Cardan, and "Opus Epistolarum" of Petrus Martyr; and adds that "birds, sheep and even some fish were killed by the shower".

Prof. H. H. Nininger, secretary of the Society for Research on Meteorites, in his book "Our Stone-pelted Planet" (The Riverside Press, Cambridge, U.S.A., 1933), chapter xvii, "Danger from Falling Meteorites", refers to a man being wounded by the fall of a meteorite at Mhow, U.P., India, on February 16, 1827, and to another being stunned by the concussion from a meteorite which fell at Nedagolla, Madras, on January 23, 1870. The cases cited by Humboldt are not mentioned in this book, possibly because no specimens from these falls are preserved or are identifiable at present.

Ward's Bulletin (vol. 3, Nos. 1 and 2, October and December 1934, Rochester, U.S.A.) invited correspondence on the subject of 'homicidal' and 'man-killing' meteorites, but the accounts of alleged recent incidents received from correspondents either did not stand the test of accurate inquiry or were much too vague to call for an investigation.

There are several accounts of narrow escapes, some of which are mentioned in Nininger's book above referred to. I may mention one from the shower of September 29, 1928, near Naoki, Hyderabad, Deccan, described in the *Journal of the Osmania University College, Hyderabad*, vol. 1, No. 2; 1934, in which an aerolite is reported to have fallen "only twelve paces" from a shepherd at Kawagam.

MOHD. A. R. KHAN.

Begumpet, Deccan,
N.S.R., India.
Aug. 29.

MOST of the cases referred to in the above letter are mentioned in Prof. Heide's book along with several others; unless the two Indian cases quoted by Mr. Khan are better substantiated than the others I must prefer to accept Prof. Heide's statement that "noch kein einziger, sicher beglaubigter Fall ist vorgekommen, dass ein Mensch von einem Meteoriten erschlagen oder verletzt worden ist".

THE WRITER OF THE REVIEW.

Social Science Investigation

CERTAIN difficulties with regard to investigation in the social sciences are discussed in the leading article in NATURE of September 14. May I point out that perhaps these are not so great as at first sight appears?

In the first place, the difficulty of social experiments is largely overcome by legislation. An Act of Parliament concerning some social problem is in the nature of an experiment in dealing with it: it is the application of forces derived from the State designed to act on a particular part of society in certain ways more or less defined according to the terms of the Act. A certain amount of control also is not altogether lacking. Knowledge is obtainable as to the condition of the part of society affected before the operation of the Act, and it is obtainable also during and after its operation over any desired period; while the changes which are thus disclosed may frequently be connected with the Act in the relationship of cause and effect. Further information, too, is to be had in many cases where legislation on similar lines has taken place in our own past history, or in the history of other countries, and something may be learned regarding the effects produced in such cases.

We may take it as tolerably certain, however, that the changes effected in society by an Act of

Parliament are seldom confined to that part which it was designed to affect: it is bound to have its repercussions for good or for harm in all parts of society. It would be in tracing these ulterior effects where the skill of the investigator would perhaps be most taxed, since they call for knowledge of, and insight into, social structures and functions which few seem to possess.

I may add that Herbert Spencer's "Descriptive Sociology" (recently completed, I believe) is a work designed to supply the sociologist with facts concerning societies at large which should be useful in formulating the first principles of the science.

Function of the Labral Glands in *Chirocephalus*

THE possible connexion of the labral glands with the feeding process in *Chirocephalus* has aroused considerable controversy (see Cannon[1]). Current work on the function of the numerous body glands in this animal leads us to the conclusion that these have the same function as the tegumental glands of the Decapoda (Yonge[2]), that is, the formation of the outer, cuticular portion, of the integument. The labral glands have essentially the same structure as the body glands and we have increasing evidence that they have the same function. We are therefore interested in the claim recently made by Cannon[1] that he has identified the secretion of the labral glands. He has directed attention to the presence in sections of an amorphous mass on either side of the labrum, over the ventral food groove and also throughout the gut, which stains with anilin blue. A very detailed study of the arrangement of this has led him to the conclusion that this must all be formed by the labral glands.

We find a number of *a priori* reasons for opposing this.

(1) The very great amount of this staining mass compared with the very small size of the glands, added to the fact that it must be poured out continuously because it is passed into the gut which, apart from the food, it fills.

(2) The difficulty of reconciling the presence of the mass outside, which Cannon claims is semi-coagulated, with the rapid movement of the appendages.

(3) The fact that multicellular glands present in the labral region in all 'Malacostraca' are certainly tegumental glands producing cuticle the presence of which is equally vital to all Crustacea.

(4) Where there is definite evidence as to the nature of the secretion of the unicellular dermal glands of the 'Entomostraca', for example, cement glands of Cirripedes, uterine glands of *Chirocephalus* (Yonge[3]), this is of the same nature as the secretion of the multicellular glands of the 'Malacostraca', for example, tegumental glands of *Homarus* (Yonge[2]), cement glands of *Homarus* (Yonge[3]), glands in statocyst of *Homarus* (Lang and Yonge[4]), nest-forming glands of *Amphithoe* (unpublished work), namely a substance of low surface tension which sets as a *hard cement* on contact with water. All the unicellular glands of the 'Entomostraca', including the labral glands, have essentially the same structure.

We have an alternative explanation as to the origin of the mass described by Cannon. This was suggested by the fact that antiperistalsis is of normal occurrence in the Crustacea. A *Chirocephalus* was kept overnight in a suspension of carmine. The gut was then red throughout and the animal was transferred to several changes of fresh water until no trace of carmine remained outside the body. It was then fixed in Bouin and observed at the same time under the binocular microscope. A series of antiperistaltic waves of contraction passed along the gut and about half the contents of the gut were regurgitated passing out of the mouth as a semi-coagulated mass which flowed forward on either side of the labrum and backward down the ventral food groove. The final appearance is indicated in Fig. 1.

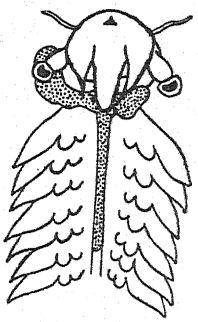

FIG. 1. Ventral view of the anterior portion of *Chirocephalus* after feeding with carmine and fixation. Regurgitated mass stippled.

Examination of sections of this animal revealed no essential difference between the distribution of this regurgitated mass and of the material described by Cannon and shown in the plate which illustrates his paper. The larger particles of carmine were the last to be extruded and occupied the position of the food, as described by Cannon, the other material, coagulated gut secretion with minute particles of carmine which gave it colour in the mass, spreading out forward on either side of the labrum and also in and below the food groove posteriorly.

We feel justified in claiming that the association of the labral glands with feeding has not been conclusively demonstrated. Prof. Cannon, with whom one of us (C.M.Y.) has had a very pleasant correspondence on this matter, is not entirely convinced by our arguments or experiments. One reason for publishing this letter is the hope that it may induce some third party, not previously committed to a belief in the secretion of the labral glands as either concerned with feeding or with the formation of the cuticle, to undertake a further study of the origin of this amorphous mass.

Multiplanar Cyclohexane Rings

WITH reference to the letter of Dr. Qudrat-i-Khuda in NATURE of August 24, we wish to state that in this laboratory, the synthesis of the 1-carboxy-4-methyl-*cyclo*hexane-1-acetic acids from the dicyano ester prepared from 4-methyl*cyclo*hexanone by Higson and Thorpe's method, led only to a pair of isomerides melting at 137° and 173° respectively. These acids proved identical with the acids previously obtained by oxidation of the isomeric α-keto-4-methyl*cyclo*-hexane-1:1-diacetic acids with hydrogen peroxide.

Since the remaining two isomerides described by Dr. Qudrat-i-Khuda were at no time encountered in

this synthesis, it was decided to repeat this work. The acids described as (*A*), (*B*) and (*C*) were isolated in accordance with this author's directions[1], but no trace of the fourth isomer could be obtained. The acids (*A*) and (*C*) proved identical with the two acids obtained by Higson and Thorpe's method, but the third isomer (*B*) was actually a mixture of (*A*) and (*C*). We thus arrived independently at the conclusion of Goldschmidt and Grafinger, that there are only two stereoisomeric forms of 1-carboxy-4-methyl*cyclo*hexane-1-acetic acid.

It may be added that we have been unable to isolate the carboxy-3:3-dimethyl*cyclo*hexane-1-acetic acid obtained from 3:3-dimethyl*cyclo*hexanone, in more than one form.

Spectrum Analysis

THE term 'spectrum analysis' was originally used to denote the analysis of substances by means of their spectra, and it would probably still be interpreted in this sense by most experimental spectroscopists. To those not accustomed to this usage, however, it seems to connote the analysis of the structure of a spectrum, for example, its resolution into series or multiplets.

Might it not be well to abandon the term 'spectrum analysis' and substitute one free from this ambiguity?

Prof. E. N. da C. Andrade suggests 'spectrochemical analysis' and Prof. W. E. Curtis 'spectroscopic analysis'. For the time being, those associated with me here will endeavour to use the former phrase, but I should be glad, as doubtless would others, if through the medium of your pages other opinions could be brought to light for our guidance.

Points from Foregoing Letters

THE reviewer of "The Diary of Robert Hooke" is criticised by Mr. T. E. James for his description of Henry Oldenburg as an "oblique, intriguing and toadying individual". Mr. James ascribes the absence of Hooke's portrait in the Royal Society to Hooke's "fickle physical condition" probably making him a difficult 'sitter'. Dr. R. T. Gunther complains of the statement that the biographer, Richard Waller, "apparently had little personal knowledge of Hooke", and points to the recently published later diaries, which indicate that Waller was frequently in the company of Hooke. The reviewer, Prof. E. N. da C. Andrade, gives some of the historical evidence upon which he has based his unfavourable opinion of Oldenburg and asks for counter-evidence. He directs attention to diary entries which suggest that a painting of Hooke by "Bonust" may perhaps be in existence.

Dr. Dingle has distinguished three aspects of probability: (i) the ordinary everyday aspect or 'likelihood' (such as the odds in betting on a horse race), usually the result of instinctive evaluation rather than of calculation; (ii) the physicist's probability, measured from past events (the favourite wins once in ten times); (iii) the mathematically derived 'chance' of future occurrences derived by combining data from independent sources such as (i) and (ii). Dr. Dingle has called the probability calculated in this way a symbolical function, meaningless from the operational point of view. W. Barrett and T. Smith take exception to the reasoning in one example adduced by Dr. Dingle to illustrate his view. Dr. Dingle restates his case in general terms and points out that the objections raised are due to misunderstandings.

Graphs indicating first a rise and then a decrease in the attenuation of radio waves in two definite directions up to a distance of 4,800 m. are submitted by Dr. S. R. Khastgir, D. N. Chandhuri and B. Sen Gupta. The authors point out that the experimental results can be accurately accommodated by Sommerfeld's formula, making use of Rolf's graphs, by giving to the two main constants values agreeing with laboratory determinations of the dielectric constants and electrical conductivities of soils of varying moisture content.

From spectroscopic and quantum-mechanical considerations, H. Lessheim and Prof. R. Samuel calculate the heat of dissociation of carbon monoxide (by Kaplan's method) and find a somewhat lower value, 10·45 v.e., than that recently calculated by Goldfinger, Lasareff and Rosen in a different manner. The corresponding heat of sublimation of carbon comes to 155·7 k.cal./mol. at 25° C.

The presence of oxygen in the sun's chromosphere up to a height of 3·5″ or more has been observed by T. Royds by means of a spectrograph. The infra-red oxygen spectrum lines, 7771, 7774, 7775, are clearly recorded.

Referring to a recent leading article in NATURE, in which the various factors needed for the development of a social science were discussed, Alan Blair points out that Acts of Parliament are equivalent to social experiments; although perfect 'controls' to such experiments are lacking, one may compare the effects produced with conditions before the passage of such Acts and with the effect of similar laws elsewhere.

Prof. Cannon, by staining with anilin blue a specimen of the fairy-shrimp, *Chirocephalus*, has observed an amorphous mass on either side of the upper border covering the mouth (labrum) over the ventral food groove, and has concluded that it was secreted by the labral glands. Miss K. W. Nicholson and Prof. C. M. Yonge, who believe that the labral glands have nothing to do with feeding but are effective in the formation of the cuticle, report an experiment in which a *Chirocephalus* was fed a suspension of carmine. After fixation, an amorphous mass similar to that observed by Cannon but due merely to the regurgitated contents of the gut was noted.

Research Items

Early Man in Palestine

EARLY man in Palestine was the subject of a report and of communications from Miss D. A. E. Garrod, Sir Arthur Keith and Mr. T. D. McCown in Section H (Anthropology) at the Norwich meeting of the British Association. Miss Garrod's excavations in caves on Mt. Carmel on behalf of the Association's committee in 1934 carried further the excavation of Tabun ("The Oven") with the object of exposing bed-rock over as large an area as possible. Further finds of animal bones now give a very good idea of the fauna of the Acheuleo-Mousterian period. Both rhinoceros and hippopotamus confirm previous indications of a warm, damp period. A new and important find was a large portion of the tusk of an elephant, the first Pleistocene elephant to be discovered in the Near East. In the artefacts the typological divisions noted in the previous year were much less marked. A steep slope of the rock and its overlying deposits complicated excavation. It became clear that this slope ended in a swallow-hole, into which the deposits had subsided. As complete excavation of the swallow-hole would be costly and lengthy, further examination was abandoned, and the excavation of the Tabun may now be regarded as complete. In the report on the remains of Mousterian man in Palestine, Miss Garrod, dealing with the culture of the people of the caves of Wady Mughara, concluded that the association of skeletal remains with implements of Levallois type and the fauna of a warm, moist climate, as contrasted with the temperate woodland fauna of later Mousterian levels, indicated that they belonged to the end of the Riss-Würm interglacial, approximately contemporary with the Ehringsdorf and Tauback remains. Sir Arthur Keith and Mr. McCown dealing with the skeletal material, both complete and fragmentary, concluded that their anatomy pointed to a variant form of Neanderthal man, which exhibits features comparable with those of the more primitive races of modern man.

Psychology of Attention

THE *Human Factor* (9, Nos. 7 and 8) has an article by Mr. Ivor Benson on attention problems in the judging of newspaper literary competitions. The author describes the work of the adjudicators, and points to it as an open field of research for industrial psychologists. It offers what is perhaps a unique opportunity for studying the problem of attention among intelligent, imaginative workers. The circumstances of adjudicating necessitate the close control of material and output which is essential to psychological investigation, but can seldom be imposed upon workers of this kind. In performing a given task, the greatest possible sensitiveness, speed and accuracy must be maintained by the adjudicator at a constant level for as long as 7½ hours. The degree of efficiency varies from day to day, both collectively and among the individual workers. In the office tested, it was found that the root cause of inefficiency was emotional disturbance. Sensory distractions were unnoticed so long as the adjudicators were in a cheerful mood, but when they were gloomy they exaggerated sounds and movements and were disturbed by them. Fear and the sense of insecurity that followed a reprimand had also an inhibiting effect, and caused them to slacken their speed in over-anxious concentration.

Sperms of Freshwater Ostracods

THE remarkable spermatozoa of certain small freshwater ostracods are known to attain a length of 6 mm., that is, ten times the length of the adult ostracod. A. G. Lowndes (*Proc. Zool. Soc.*, London, Part 1, 1935) records the results of his observations on the spermatozoa of certain British ostracods with particular reference to their motility. He points out that motile sperms can be obtained only from the spermatheca of a female specimen, and that comparatively few females ever contain sperms, because parthenogenetic reproduction is prevalent. All attempts to obtain motile sperms from males were unsuccessful. Each sperm consists of a long thin pointed part which the author has observed to be anterior in movement, and a thicker cylindrical portion—the flagellum; Retzius and other previous observers regarded the thicker portion as anterior. Mr. Lowndes states that ripe eggs placed in a drop of fluid containing sperms are not attractive to the sperms; the entry of the sperm into the egg has never been described in ostracods. The thin anterior part of the sperm appears as a long central rod with a thin hyaline band twisted round it, and at its tip a small rounded knob, suggesting an acrosome. The flagellum has the appearance of a twisted cable, as there are two spiral bands. Throughout the entire length of the sperm is a central spiral thread, which in the flagellum is twisted round an axial strand. The sperm is enveloped in a thin hyaline membrane. Definite information as to the nature of the nucleus is lacking. Three kinds of movement of the sperm are described—rotation, undulation and ripple movement. The author points out that in many species of ostracods males are unknown, but the spermathecal ducts are present in the females, and there is no evidence that they are undergoing reduction. He regards the highly complicated copulatory apparatus and the abnormal sperms as having ceased to have any real function.

Watermark Disease of the Cricket-Bat Willow

DR. W. J. DOWSON described a serious disease of *Salix cærulea*, the cricket-bat willow, to the members of Section K (Botany) at the Norwich meeting of the British Association. The malady causes death of the tops, induces a greyish stain or watermark in the wood, and in all is responsible for a loss of something like £150,000 to the growers in Essex. Mr. Day, of Oxford, originally named the causal organism *Bacterium salicis*, but Miss Lindeijer, working in Holland, obtained a slightly different pathogen, which she named *Pseudomonas saliciperda*. Dr. Dowson now confirms Day's naming, so far as the disease in Essex is concerned, though a harmless organism with all the characters of *P. saliciperda* has also been found. Control measures suggested were mainly concerned with the extension of legislation to prevent spread of the disease.

Dating of Scottish Varved Clays

MEASUREMENTS made by Dr. J. B. Simpson of fifty-nine varves in a deposit near Dunning in the Earn valley south-west of Perth form the basis of an attempt by Baron De Geer to fix their absolute age (*Proc. Roy. Soc. Edin.*, **55**, 23; 1935). After a systematic comparison, De Geer has succeeded in matching the thickness-variation diagram of the varves with that of a series from the neighbourhood of Copenhagen. This indicates that the Dunning varves represent the years 4313–4371 before the zero year of the Ice Age, which itself occurred about 8,700 years before our century. Thus the measured varves were deposited during the earlier part of the Goti-glacial sub-epoch when the Scandinavian land-ice still filled the whole of the Baltic depression. That the varved clays near Perth are often moraine-covered may be explained by oscillations of the ice-border during its recession. Further measurements are necessary to determine whether varve-deposition was going on during the extension or the recession of the ice-border.

Natural Gas Conservation

THE trend of chemical research to-day indicates that, quite apart from its particular and well-known function in the production of oil, there is a wide field of usefulness for natural gas as a basic raw material in the manufacture of dyestuffs, solvents, anæsthetics, etc. Its conservation, therefore, is of paramount importance. Gas found in intimate association with commercial accumulations of oil has for some time past been conserved, so far as economically practicable, and a wealth of literature has emanated on this aspect of the subject. Mr. C. T. Barber, in his work on "The Natural Gas Resources of Burma" (*Mem. Geol. Surv. India*, **66**, part 1, 1935), takes a less familiar point of view, and stresses the importance of conservation of gas not found in association with oil. Of the vast natural gas resources of Burma, he points out, a considerable proportion is not in intimate association with commercial accumulations of oil. Some of this actually occurs in structures not containing, or not known to contain, oil, while some is found either as free gas in the crestal portions of oil-bearing sands or in non-oil-bearing beds in structures yielding oil from other horizons. In addition to problems of gas conservation, Mr. Barber's work includes a brief outline of the Tertiary geology of Burma, and detailed accounts of the principal natural gas fields, their geographical situation, stratigraphy, and approximate production. Useful maps and an up-to-date bibliography complete this latest work on natural gas in Burma.

Magnetic Testing of 'Work-Hardening' Steel Wires

THE testing of the steel wires used in colliery 'winding' and 'haulage' is of great importance. It is well known that the so-called 'work-hardening' of a wire rope is as great a menace to its safety as the actual mechanical fracture of a group of the component wires of a rope. In a paper which appeared in the *Engineer* of September 13, Dr. T. F. Wall, of the University of Sheffield, points out that only to measure the elasticity of the wires is not a sufficient criterion of their condition. Another characteristic quantity of the greatest importance is the viscosity of the metal forming the wires. There appears to be two kinds of viscosity, one associated with simple longitudinal stresses and the other type associated with a travelling surge of stress in the wire. Dr. Wall describes two electromagnetic methods. The first uses the magneto-striction effect for measuring Young's modulus for a wire by means of longitudinal vibrations. The other is to measure directly the speed at which a surge of stress travels along the wire. Experiments show that the former method provides a very sensitive means for detecting small effects of magnetic loading which cannot be detected in any other way. Work-hardening results in a relatively greater magnetic response to small stresses and a relatively smaller magnetic response to large stresses. The second method measures the velocity of a surge stress by passing the wire through several solenoids connected in series and at the centre of each of which is a search coil connected with an oscillograph. Oscillograms are taken with different magnetising forces and the one which shows that the magnitude of the induced E.M.F. in the search coils varies logarithmically gives the rate of decay of the surge itself. Knowing the velocity of the surge, Young's modulus can be found.

Activity Coefficients from Electromotive Forces

THE electromotive force of a cell containing two solutions of a uni-univalent salt at different concentrations is given by the equation $E = -(2tRT/F)\log(a_1/a_2)$, where t is the transport number and a activity. When, as is usually the case, t is a function of concentration, this must be replaced by $E = -(2RT/F)\int t.d\log a$, the integration being over the range of concentrations used. This equation has been used to find transport numbers, but now that accurate values of the latter are known, it can, as A. S. Brown and D. A. MacInnes (*J. Amer. Chem. Soc.*, **57**, 1356; 1935) show, be used in the determination of activities. The potential is known to be very reproducible and independent of the method of formation of the liquid junction, and this has been further confirmed by measurements with sodium chloride solutions. The electrodes were of silver and silver chloride. If the activity is expressed as the product of concentration (c) and activity coefficient (f), the values of the latter can be very well represented by Hückel's equation: $\log f = -\alpha\sqrt{c}/(1+\beta\sqrt{c}) + Dc$, where α, β and D are constants. It was, however, necessary to change the theoretical value of β from 1·463, as obtained by extrapolation at high dilutions, to 1·315. The value 1·463 corresponds with a 'distance of closest approach' of the ions of 4·45 A., which is sufficiently large to make the higher terms in the extended theory of Gronwall, La Mer and Sandved negligible. The equation proposed by Hitchcock, $-\log f = \alpha\sqrt{c} - Bc$, did not give satisfactory results. Harned and Nims have published results for activity coefficients of sodium chloride obtained with amalgam cells not involving liquid junctions, and these fall on the same curve as the present ones if they are adjusted so as to coincide at 0·1 N concentration. The values of the Hückel constants found by Harned and Nims for the more concentrated solutions used do not, however, agree with those found with dilute solutions by Brown and MacInnes, whose results extend to 0·05 N.

ERRATUM. In the paragraph entitled "Structure of Keratin" (NATURE, Oct. 5, p. 557, lines 21 and 22), for "were respectively normal and parallel to the flat surface" read "were respectively parallel and normal to the flat surface".

Sixth International Botanical Congress

AMSTERDAM MEETING

ABOUT nine hundred members, including delegates from more than fifty countries, attended the sixth International Botanical Congress at Amsterdam in the first week in September. The much-regretted death of Prof. F. A. F. C. Went had, a few weeks previously, deprived the Congress of its president. His place was taken by Prof. J. C. Schoute, who, in welcoming the members at the opening meeting, referred to the great loss to botany and to their regret that the directing hand had been unable to carry the work to completion.

The papers in the various sections were given by invitation of the executive committee, and were grouped under headings. A great variety of subjects were included, of special and general interest, the latter often affording combined meetings with other sections. Thus the evolution of angiosperms interested palæobotany and taxonomy, flower morphology attracted taxonomists as well as morphologists, and "Taxonomy and Genetics" had an obvious dual interest. Joint discussions were indicated between cytology and genetics, between each of these and mycology, between agronomy and phytopathology or physiology and so on. The programme, a marvel of condensation in three languages, informed members as to subject, date and place of meeting, and a volume of abstracts of the papers provided a useful handbook. Members interested in special studies found opportunity for informal meeting and discussion.

The Nomenclature Section of Taxonomy, under the presidency of Dr. Merrill, worked through a series of proposals, the main purpose of which was to clarify points, where desirable, in the recent edition of the "Rules of Nomenclature". Certain additions suggested by the palæobotanists to meet difficulties, arising especially from the fragmentary character of the material, were accepted.

An admirable "History of Botany in the Netherlands" had been prepared by the senior secretary, Dr. M. J. Sirks, and a pamphlet by Prof. Leeuw described in detail the Netherlands as an environment for plant life.

Linnæus was a student at Leyden, and his early botanical work was done in Holland. The bicentenary of the publication of his "Systema Naturæ" (Leyden, 1735) was commemorated by an appropriate exhibit of Linneana at Amsterdam during the Congress.

Days reserved for excursions gave opportunity for visiting botanical laboratories and gardens, as at Utrecht, Leyden, Baarn. Special care was taken by those in charge to make the visits instructive and interesting. The botanical garden at Leyden is one of the oldest in Europe. Founded in 1587, it was laid out under the supervision of Clusius in 1594, and members were shown a replica of his garden recently prepared from an original plan and inventory. More than 1,000 species and varieties were represented, and it showed a character, novel for the time, of a botanical, not merely a medical, garden. At Baarn, the extensive collections of pure cultures of fungi, amounting to 5,000 units, under the care of Dr. Joh. Westerdyk, were visited and at Lisse the admirably equipped bulb research laboratories.

A drive along the old Zuyder Zee and on the dam which now holds back the North Sea was an object lesson in the essentially Dutch art of converting sea-flooded areas into cultivable polderland. Various stages in conversion were seen, culminating in a polder bearing crops and two new villages which five years ago was open sea.

Pleasant social functions were evening receptions by the Netherlands Botanical Society, and, at the Rijksmuseum, by the Netherlands Government; the latter gave opportunity of inspecting the famous picture galleries.

At the final plenary meeting, an invitation from Sweden to hold the meeting in 1940 at Stockholm was accepted. An invitation to meet in South Africa had been withdrawn.

The executive committee is to be congratulated on its successful organisation; special mention is due to the senior secretary, Dr. M. J. Sirks.

A. B. RENDLE.

Twelfth International Congress of Zoology

LISBON MEETING

IN view of the restrictions on foreign travel imposed in several European countries it was expected that the number of members attending the Congress of Zoology which was held at Lisbon on September 15–21 might fall short of that reached at some previous meetings of the Congress. In the event, however, the number proved to be little, if at all, less than that of the last meeting at Padua in 1930. Under the presidency of Prof. Arthur Ricardo Jorge, some five hundred members took part, and the programme showed about two hundred separate communications to be read either before the full Congress or at the sessions of the twelve sections into which it divided.

At the opening meeting, presided over by the President of the Portuguese Republic, the Minister of Public Instruction welcomed the Congress and delivered an address on the place of biology in education, in which he advocated instruction in the principles of biology as a necessary preparation for the teaching of ethics, civics and even politics.

It is not possible here to enumerate even the more important of the communications made to the Congress, but one or two may be mentioned which, for different reasons, happened to interest members of the British delegation. Prof. R. Anthony (Paris) gave an address on the evolution of the molar teeth in mammals, in the course of which he criticised

once again the much criticised 'tritubercular theory'. In this, he was supported by Mr. Hinton, of the Zoological Department of the British Museum. Prof. R. Goldschmidt (Berlin) gave an account of the progress of his long-continued researches on the genetics of local races of the gipsy moth, and came to the conclusion that local races do not represent a stage in the evolution of species. Prof. Przibram (Vienna) demonstrated living specimens of a stick insect in which transplanted legs were voluntarily movable, although sections of similar specimens failed to reveal any connexion with the central nervous system.

Dr. Calman directed attention to the centenary of Darwin's visit to the Galapagos Islands and to the action of the Government of Ecuador in declaring certain of the islands a Nature reserve. The Congress adopted a resolution expressing its appreciation of the step taken by the Ecuadorian Government and offering its co-operation in any further action that might be necessary to preserve from extinction the very interesting fauna of the islands.

Probably no section of the Congress worked harder than the members of the International Commission on Zoological Nomenclature who sat (mostly in their shirt-sleeves !) for several hours each day under the chairmanship of Dr. Jordan of Tring, striving to disentangle the complexities of the problems submitted to them. For the first time in many Congresses, they met without their indefatigable secretary, Dr. C. W. Stiles, of Washington, who was prevented by illness from travelling to Lisbon. The result of their labours was the addition to the official list of *nomina conservanda* of a considerable number of generic names, mostly of insects, that were threatened with displacement or transference by a strict application of the rule of priority.

Unfortunately, some of the rooms where the meetings were held proved defective in their acoustic qualities. In particular, the lofty hall used for the plenary sessions, being lined with polished marble, provided an excellent demonstration of the reflection of sound. Since each speaker used a language which was foreign to some eighty per cent of his audience, effective discussion was impossible except where an abstract of the paper had been supplied beforehand. It is to be hoped that at future Congresses an attempt will be made to print abstracts of all papers and to distribute them well in advance of the opening day, and perhaps even to supply the full text of the more important addresses.

Finally, mention should be made of the lavish hospitality shown to the Congress by the Portuguese Government, the Municipality and the University of Lisbon, and the Municipality of Sintra, as well as by the Portuguese zoologists themselves. Many northern zoologists, making acquaintance for the first time with the brilliant sunshine, the blue sea, and the subtropical vegetation of Portugal, will not soon forget the friendliness of their Portuguese colleagues.

International Meteorological Conference

WARSAW MEETING

THE International Meteorological Conference is an assembly, which meets every six years, of the directors of meteorological services in all parts of the world. A meeting was due in 1935, and by invitation of Dr. J. Lugeon, director of the National Meteorological Service of Poland, it was held in the Palais Stasjic, Warsaw, on September 6–13 under the presidency of Prof. E. van Everdingen. The conference was formally opened by the President of the Republic of Poland on September 6, and an address of welcome was delivered by the Minister of Communications. Only directors can be members of the full conference, but much of the detailed work of organisation is carried out by commissions nominated for special subjects, and each commission is composed of those meteorologists who are most expert in the work of the commission. Meetings of nearly all the commissions were held either in Warsaw before and during the main conference, or in Danzig during the preceding week.

The work of the conference and commissions covers a very wide field—synoptic meteorology, investigation of the upper air, climatology, agricultural meteorology, maritime meteorology, terrestrial magnetism, bibliography, etc., with many ramifications of detail. Synoptic meteorology, including the taking of observations at agreed hours, their broadcasting in code, reception and plotting on charts, has required the building up of an international organisation of great complexity, which is of vital importance not only for daily weather forecasting, but also for aviation. The extension of regular long-distance flying, in particular, has had the result that pilots pass from one country to another, and need to consult a variety of different weather charts, not only for the general isobars and winds, but also for details such as the form and height of clouds, or the presence of fog, thunderstorms, etc. To avoid confusion, the observations must be made and coded in a uniform manner —for which purpose detailed instructions in the use of the codes have been drawn up for international use. It is equally important, however, that the weather reports should be entered on the weather charts of different countries, according to a general plan, so that the pilot knows at once exactly where to look for the particular information which he requires. This 'station model', as it is termed, has been the subject of very careful consideration at Warsaw by the Commission for Synoptic Weather Information, and a great measure of agreement has been arrived at as to the form which it should take.

Another subject studied by this commission also concerns the international language of meteorology, namely the symbols used to represent various meteorological phenomena. At Warsaw, several new symbols, especially one for drizzle, were added to this international language. Finally, among a number of minor improvements in the codes for weather reports must be signalised the beginning of the arrangements for the inter-continental exchange of weather information by wireless, with the view of preparing within a few hours daily weather

charts for a hemisphere, if not for the whole world.

The great importance of weather in aviation necessitates close relations between meteorological services and the authorities in charge of air lines. To meet this need, the conference at Warsaw formed a new commission, the purpose of which is to keep in close touch with the requirements of aviation, and to maintain and develop as required the meteorological organisation necessary for this purpose.

Another aspect of synoptic meteorology to which reference must be made is the construction of detailed daily charts of the northern hemisphere, now being prepared by the Deutsche Seewarte with international co-operation for the whole period of the Polar Year 1932–33. As reported by the Polar Year Commission, the preparation of these charts is progressing, though difficulty is being experienced in obtaining data for some of the more remote parts of the northern hemisphere. When completed, these charts will be of the greatest value for studies in dynamical meteorology.

The tendency towards internationalisation has appeared also in the domain of climatology, in the form of an international 'alphabet' for the headings of columns. Thus the column, for example, for 'pressure' in a climatological table should bear the letter *P*, no matter what country issues the table. The Climatological Commission has also devised a standard form of table for the guidance of meteorological institutes. Months are designated I–XII, but both in climatology and in agricultural meteorology the need has been felt for the use of a unit of time shorter than a month and there has been great discussion of the relative advantages of the 5-day period, or pentad, and the week, with the result that both units have received international approval.

The Commission for Terrestrial Magnetism and Atmospheric Electricity was occupied mainly with questions of detail. Among the resolutions were also appreciations of the action of the British Admiralty in deciding on the construction of a non-magnetic ship specially designed to carry on the researches formerly made on the ill-fated *Carnegie*, and of the Canadian authorities in transforming the temporary geophysical station erected at Chesterfield Inlet for the Polar Year into a permanent station.

The report of the Commission for Bibliography, which was unanimously adopted by the conference, presented a new plan of classification for meteorological literature, affiliated to the decimal classification of the International Institute of Bibliography, but thoroughly revised. This classification has been studied and discussed for several years, and its completion will greatly facilitate bibliographical work in meteorology.

The work of an international conference does not end with the formal debates and resolutions; there remain many problems which can only be resolved by private discussion among the members. The value of the Warsaw conference was greatly increased by the presence of delegates from all parts of the world. Africa was especially well represented, and the practical problems of organisation in that difficult continent were fully explored.

On Sunday, September 8, an all-day excursion was made to the new aerological and radiometeorological observatory at Jablonna, which owes its inception to Dr. Lugeon, and which promises to be of as great importance in studies of the ionosphere in Poland as is the station at Slough, in England. On the evening before the final meeting, H.E. the Minister of Communications entertained members and their wives to a State banquet, where all speakers reflected the spirit of optimism prevailing in meteorology to-day, which was the keynote of the whole conference. After the meeting, many of the delegates proceeded to Cracow and the Tatra Mountains on an excursion which was admirably organised and provided an experience not readily to be forgotten.

Biochemistry in Relation to Therapeutics

SIR FREDERICK GOWLAND HOPKINS delivered the inaugural sessional address at the opening of the ninety-fourth Session of the College of the Pharmaceutical Society on Wednesday, October 2. His address included a wide survey of the needs of pharmacy to-day and of the educational means for satisfying them, and led him to examine a problem as old as education itself, the problem of how far vocational training is compatible with true education in which a subject is studied for its own sake as an intellectual exercise. It has often been said that science can only be taught properly when it is taught as pure science without reference to its applications. This claim is justified to the extent that vocational needs must not make the teaching of science so one-sided that the student risks missing the intellectual stimulus which the great generalisations of science provide.

Teachers of applied scientific subjects will be grateful to the president of the Royal Society for his declaration that the skilful teacher of students whose ultimate aim is to apply science in practice, can illustrate general principles adequately while selecting facts and aspects which have a permanent vocational value. Indeed, for the encouragement of the average student, it is important that the reality of this permanent value should be part of his faith. Without it he can never be an enthusiast for his calling. The preference for vocational training may well be based on the Anglo-Saxon preference for action rather than thought and for practice rather than theory, but it is an attitude of mind having in it the seeds of certain dangers. Indeed, a distrust of theory has sometimes kept Great Britain from being in the van of intellectual and not less of commercial progress: "It was because it had become really scientific that the medical knowledge of another country received for a long period and up to the time of the War the greatest respect in the world and it was because its chemists were so fully trained in theory that the same country obtained among other similar advantages a long lead in the production of synthetic drugs which rightly or wrongly brought it enormous profits".

On the same occasion Sir Frederick Gowland Hopkins took occasion to review the present state of biochemistry; in particular, in its relation to

therapeutics. As he pointed out, while the structure of a drug administered as a medicine may be known, very little has been known about the nature of the events in the tissues of the body which are affected by the drug. The pharmacologist relies upon the obvious and visible reaction of the body as a whole to the drug when administered, or at least, of the reaction of a specific organ as a whole. His observations throw little light upon the precise and intimate mechanism of the drug's action. This is the province of biochemistry, and modern biochemistry is fast acquiring methods which enable it to follow the progress of the invisible molecular events which occur in the tissues while they are living.

Biochemistry should in the future be able to describe in detail the numerous chemical reactions which proceed in ordered sequence in every living tissue cell. The great majority of drugs act by intruding among these chemical reactions and by modifying their course or by entering relations with the enzymes which catalyse these reactions. When we know into what kind of reaction and at what stage in its progress a given kind of molecule intrudes, or when we know exactly the chemical nature of the enzyme with which, owing to mutual structural affinities, it makes sufficient contact, then we shall be in a better position for understanding just why the details of its molecular structure confer upon each drug a particular physiological activity. Biochemical investigation of the relationships of the vitamins and hormones has led to the view that it is nearly, if not quite, justifiable to look upon a vitamin as a hormone which the body cannot make for itself, or on a hormone as a vitamin which it does make for itself.

Educational Topics and Events

ST. ANDREWS.—Mrs. Low of Blebo has given £1,000 to the University for the purpose of founding in memory of her son, the late Capt. W. A. Low, a Gold Medal and prize to be awarded annually to the student adjudged to have had the most distinguished course among those graduating in the year as M.B.,Ch.B. The foundation will be named "The Captain W. A. Low Memorial Prize".

The Court has appointed Dr. James A. Macdonald to be a lecturer in botany in the United College.

Dr. James F. Murray, lecturer in bacteriology in the Medical School, Dundee, having resigned that post, the Court has appointed Dr. Alexander B. Stewart, presently assistant in the Department, to the vacant lectureship.

In the old Parliament Hall, St. Andrews, on Friday, October 4, Dr. E. T. Copson was inducted to the chair of mathematics and Dr. R. C. Garry to the chair of physiology, both in University College, Dundee.

AMONG the university extension and tutorial classes arranged by the University Extension Committee of the University of London is a series of lectures on the human mind to be delivered by Prof. Cyril Burt in the City L.C.C. Literary Institute beginning on January 15, and a series on recent discoveries in psychology by Dr. C. E. Allen being given in the lecture hall of the public library, Croydon, which began on October 9. Other lectures on psycho- [illegible] ing delivered by Mr. E. Miller, Mrs. G. R. B [illegible] ite and Mr. C. E. M. Joad, at Morley College, and the Rev. F. E. England in Whitefield's Central Mission. Apart from these courses in psychology, the only other series of lectures of scientific interest is that by Prof. W. B. Brierley on the biological sciences and modern problems at Gresham College, which began on October 2. A complete list of the lectures can be obtained from the University Extension Registrar, University of London, South Kensington, S.W.7.

THE appeal for new buildings for Birkbeck College (University of London) was launched at a meeting arranged by Lord and Lady Luke at 29 Portman Square on October 2. Lord Luke, chairman of the Appeal Committee, announced that His Royal Highness the Duke of York has consented to accept the presidency of the College and will be present with the Duchess at a meeting at the Mansion House on November 7 when the Lord Mayor and Mr. Ramsay Macdonald, both old students of the College, will speak on the needs of Birkbeck. Mr. Hichens, chairman of the Governors, referred to the grant by the University of London of space for the new buildings on the University site in Bloomsbury, and Dame Helen Gwynne-Vaughan spoke of the good work of Birkbeck students. As is well known, Birkbeck College is a school of the University of London for evening and part-time students who are prevented by their employment from attendance at a college during the day. In the Science Departments, an increasing number of students come from large research laboratories under the auspices of the Department for Scientific and Industrial Research or of private firms. A special feature of the College is the strength of the postgraduate work; each year sees the publication of numerous contributions to knowledge resulting from the work of staff and students. Opportunity for investigation is given to a large number of capable men and women.

IN university circles in the United States there is widespread anxiety as to the curtailment of academic freedom. Leaders in the learned world denounce the 'brutal tyrannies' under which in more than one foreign country the expression of opinions and even the dissemination and discussion of information in universities have been stifled. Of three graduation addresses by the presidents of Harvard, Yale and Princeton, respectively, published in *School and Society* of July 13, two contain such denunciations, and one disparages the extravagant faith, so common in this age, in the efficacy of idealised social systems such as Communism and Fascism as devices for lifting humanity by its own bootstraps. A week earlier, the well-known chancellor (S. P. Capen) of another university held forth on a similar occasion on "The Obligation of the University to American Democracy". He contrasted the functions of universities in countries such as Italy, Germany and Russia, where there are dictatorships, and in democratic countries. In the former these functions have been simplified and the universities have become, in so far as they concern themselves with the social sciences, organs of propaganda. In the latter, in so far as they are true to democratic principles, the method of the propagandist is abhorrent to them. Nevertheless, in the United States alone among democratic countries, the procedure of universities in this respect is, we are told, challenged and they are constantly being attacked for "teaching socialism or pacifism or atheism or communism, or all of them together".

Science News a Century Ago

Captain Back's Arctic Expedition

The Times of October 13, 1835, contained a statement by William Bowles, the chairman of the Arctic Land Expedition, to the subscribers who financed the expedition. In the course of the statement, he reviewed the circumstances which led to the project of sending out a party to find Captain Ross, referred to the eminent services of Captain Back, his companion Mr. King the surgeon and to the assistance given in the United States and Canada and to the eight men who had made the boat journey to the coast with Captain Back. The subscriptions, Mr. Bowles said, included £2,000 from the Government, £500 from the Hudson's Bay Company, £105 from the Lord Mayor and Corporation of London, £105 from the Committee of Lloyds and £100 from the Corporation of Trinity House. "The Committee," he said, "has the highest possible gratification in announcing that, on the recommendation of the Lords Commissioners of the Admiralty, His Majesty in Council has been pleased to grant an order, dispensing in Captain Back's case, with the actual service afloat, which according to the rules of the Navy, would have been otherwise requisite to qualify him for a step in his profession. He has thus been promoted in the most gracious manner, without delay; and a munificent individual (Robert Holford, Esq., of Westcliff, Isle of Wight) has remitted 100£ to be divided in equal shares among his boat's crew, the partakers of his greatest difficulties and dangers".

Lyell and Mantell

SHORTLY after his return home from his tour in France, Switzerland and Germany, Lyell on October 14, 1835, wrote from London to Dr. Gideon Mantell at Brighton giving him an account of some of his geological excursions. In the course of his letter, he said: "I entered Switzerland by Porrentrui, and there I had Thurmann for my guide, who gave me in a short time a beautiful insight into the structure of the Jura . . . and I was glad to verify his observations in the field, and to see his beautiful collection of Jurassic shells, and his attempt to assimilate the oolitic series and their fossils of the Swiss Jura with our English oolitic groups. I afterwards had a work in another part of the Jura with some geologists at Neuchâtel, where the chalk, as it appears to me by its fossils, fills the bottom of the valleys of the Jura limestone. I next had a work with Studer at Berne, and then had a work of about six weeks in that part of the Swiss Alps which is called the Bernese Oberland. . . . People seem to be in high spirits here on the success of the Dublin meeting. Agassiz looks in good health, and is satisfied with the great progress he has made, and looks forward with great pleasure to a first visit to Brighton. . . . I have been writing this by candle-light after the labours of the day, and as you know my eyes of old, you will excuse its not being in my own handwriting. . . ."

Prof. Tiedemann in Edinburgh

ON October 17, 1835, quoting from the *Scotsman*, *The Times* said: "The celebrated Professor Tiedemann of Heidelberg has been in Edinburgh for some days. He is collecting materials for a work on the comparative anatomy of the brain and has visited London, Glasgow and Dublin. In Edinburgh he has pursued his researches in the Museum of the Royal College of Surgeons, the College Museum and the Museum of the Phrenological Society, which last he has visited on three successive days for the purpose of weighing and measuring the skulls of different nations". Tiedemann, who was born at Cassel in 1781 and died in 1861 at the age of seventy-nine years, was made professor of zoology, anatomy and physiology at Heidelberg in 1816.

Societies and Academies

PARIS

Academy of Sciences, August 26 (*C.R.*, **201**, 461–476). MARCEL DELÉPINE: The work of the late Antoine Nicolas Guntz. PIERRE DE VANSSAY: Drawing the azimuth line on a Mercator projection. S. CARRUS: The successive evolutes of a skew curve. ARNAUD DENJOY: Groups of homographic substitutions. RAPHAËL SALEM: The generalisation of certain lemmas of Van der Corput and applications to trigonometrical series. MARCUS FRANCIS: The electrolytic method of preparing thin deposits of U_3O_8. Starting with a salt of uranium not carefully purified, other radioactive substances deposit first during electrolysis and a satisfactory deposit of uranium oxide cannot be obtained. LUBOMIR DONTCHEFF and CHARLES KAYSER: The signification of respiratory coefficients below 0·7 in certain pœcilotherms.

September 2 (*C.R.*, **201**, 477–492). HENRY GAULT and MATUS COGAN: Formyltropic ester. This is produced by the condensation of formylphenylacetic ester with formaldehyde. FRANÇOIS DUPRÉ LA TOUR: Polymorphism in the series of the normal fatty diacids. JACQUES DE LAPPARENT: An essential constituent of fullers earth. HENRI LONGCHAMBON: The essential mineralogical constituents of clays, and especially of fullers earth. ANDRÉ CAILLEUX: Traces of important interglacial aerial action in Poland. GEORGES BOURGUIGNON: Chronaxy in voluntary movement and in pain in normal man. Static chronaxy and dynamic chronaxy. MME. ISABELA POTOP: Researches on the acid-soluble phosphorus, the mineral phosphorus and the ultrafiltrable phosphorus of the blood.

September 9 (*C.R.*, **201**, 493–508). The president announced the death of LÉON FREDERICQ, *Correspondant* for the Section of Medicine and Surgery. PAUL LÉVY: The law of large numbers for connected variables. G. PFEIFFER: A special method of integration of complete systems of linear partial differential equations of the first order of an unknown function. ARNAUD DENJOY: The geometry of homographic groups. ANDRÉ BRIOT and BORIS VODAR: The absorption spectra in the ultra-violet of gaseous, dissolved or liquid ammonia. PIERRE DONZELOT and MAURICE CHAIX: The Raman spectra of substances with two benzene nuclei. The substances examined included diphenyl and compounds of the type $C_6H_5.X.C_6H_5$, where X was CH_2, O, S, Se, CH(OH) or Hg. MLLE. BERTHE BIECHELER: The existence of a chromatic cyclosis in the peridineans. JOSEPH KAHN and MME. LUBOV CHEKOUN: The disengagement of ammonia by the brain, following a state of natural stimulation.

AMSTERDAM

Royal Academy of Sciences (*Proc.*, **38**, No. 7, September 1935). C. U. ARIËNS KAPPERS: Stability and variability of Central and Palæo-Asiatic index maxima and some remarks on the Greenland Eskimo. G. VAN ITERSON, JR. and J. COUMOU: A few remarks on the iodine-amylum reaction. Discussion of the nature of the blue complex and observations of the temperature of gelatinisation of starch in the presence of iodine and potassium iodide, separately and together. A relatively large rise of the gelatinisation temperature was observed in the last case. J. A. SCHOUTEN and J. HAANTJES: On general conformal geometry in projective treatment. A. A. NIJLAND: Mean light curves of long period variables. (24) *R. Lacertae*. The light of this star varies with a period of 299 days and an amplitude of 5·07 magnitudes. H. R. KRUYT and H. G. BUNGENBERG DE JONG: Extension of the theory of complex coacervation to ionic disperse systems. Experiments showing that coacervation (unmixing) occurs not only in colloidal solutions but also in supersaturated solutions of electrolytes. MISS A. M. HARTSEMA and A. H. BLAAUW: Shifting of periodicity by means of high temperatures. Adaptation and export to the southern hemisphere (2). By keeping daffodil bulbs at 28° until the next spring they can then be exported to the southern hemisphere to flower in late August. J. H. GISOLF: A demonstration experiment concerning the use of a Lummer plate. Shows the resolving power is markedly dependent on the direction of polarisation of the incident light, being greatest when the electric vector is parallel to the plane of the plate. A. ELLIOTT: A note on the β bands of boron monoxide. Data on the magnitude of the spin doubling in these bands, the existence of which had been questioned by Funke and Simons. V. HLAVATY: On conformal geometry (2). Applications particularly to the problem of the affine normals. C. S. MEYER: Integral expressions for Lommel and Struve functions (2). J. W. A. VAN KOL: Correction of some numbers of biquadratic space-curves of the first kind. There are 540 curves k^4 which meet four given straight lines. F. W. WENT: Coleoptile growth as affected by auxin, aging and food. Experiments on the function of auxin in which the auxin content is artificially increased. E. FREY: Experimental researches on the nucleus basalis opticus in the porpoise. E. FREY: The nucleus basalis opticus of the porpoise. T. KUROTSU: On the nucleus magnocellaris periventricularis in reptiles and birds. H. G. BUNGENBERG DE JONG and J. BONNER: Phosphatide autocomplex coacervates as ionic systems and their relation to the protoplasmic membrane. Suggests that the special properties of the protoplasmic membrane depend upon one or more double layers of oriented phosphatide ions similar to the double films of the phosphatide auto-complex coacervate.

CAPE TOWN

Royal Society of South Africa, July 17. A. J. H. GOODWIN: Recent changes in terminology in European prehistory. The term Clacton has been introduced in Europe to cover a flake culture which divides the Chellean and Acheulean. When Gabriel de Mortillet first organised the prehistoric period of France into a single chronological scheme, the site at Le Moustier shelter was made the type site of a major period. Later work by Commont on the gravels of the Somme River necessitated the introduction of the term Levallois to cover part of the complex present at Le Moustier. Recent work by Dr. Ami at Combe Capelle, and by Henri Martin at La Quina have rendered a further analysis necessary. As a result, the Le Moustier site is now regarded as presenting three cultural themes, which here mingle: the Levallois, the true Moustierian, and the Acheulean tradition. Afterwards Péyrony, Breuil and others have shown these themes in their earlier forms, and terms have been applied to cover these developments.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Sunday, October 13

BRITISH MUSEUM (NATURAL HISTORY), at 3 and 4.30.—Dr. Susan Finnegan: "Spiders".*

Monday, October 14

BRITISH MUSEUM (NATURAL HISTORY), at 11.30.—Capt. Guy Dollman: "Egg-Laying Mammals".*

UNIVERSITY OF LEEDS, at 5.15.—E. O. G. Turville-Petre: "Iceland".*

Tuesday, October 15

UNIVERSITY COLLEGE, LONDON, at 3.—Prof. B. Ashmole: "Greek Sculpture".*

KING'S COLLEGE, LONDON, at 5.30.—A. Ramsay Moon: "Electric Welding as Applied to Structural Work" (succeeding lectures on October 22 and 29).*

GRESHAM COLLEGE, at 6.—A. R. Hinks: "Our Sun's Neighbours" (Gresham Lectures on Astronomy. Succeeding lectures on October 16, 17 and 18).*

BRITISH INSTITUTE OF PHILOSOPHY, at 8.15.—(in University College, Gower Street, W.C.1).—The Right Hon. Sir Herbert Samuel: "New Science and Old Philosophy". (Presidential Address.)

Wednesday, October 16

SOCIETY OF GLASS TECHNOLOGY, at 2.—(at the University of Sheffield). B. P. Dudding: Presidential Address.

Thursday, October 17

BRITISH INSTITUTE OF RADIOLOGY, at 8.—(in the Reid-Knox Hall).—L. A. Rowden: "Looking Backward and Looking Forward" (Presidential Address).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, at 8.15.—Sir Arthur Bagshawe: Presidential Address.

Friday, October 18

ROYAL ASIATIC SOCIETY, at 4.15.—Prof. John Garstang: "Further Discoveries at Jericho".

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS, at 6.—Dr. John T. Batey: Presidential Address.

Preservation of Game Animals of the British Empire

A STRAIGHT problem faces the rulers of every part of the British Empire: Is the wild fauna to be left to take its chance at the hands of a native population which has been accustomed to kill without restraint, and in face of the steady encroachments of agriculture, commerce and sport, or is it to be shielded for its own sake and for the sake of posterity? And everywhere the answer is that it must be shielded. Thus a second and more difficult problem is born: To what extent and intensity must protection be carried? For it need scarcely be said (in spite of protection's ultra-enthusiasts) that where a clash arises between wild fauna and human survival or progress, mankind and not its unwitting opponents must have the backing of the State.

Rational legislation for the protection of wild animals (and the protection of the people) must, therefore, endeavour to arrange for preservation without undue multiplication where an animal is already on the down-grade, and for opportunities of destruction—falling far short, it may be hoped, of extinction—where an animal is interfering with the reasonable progress or comfort of humanity. There are few countries in which such rational legislation is in force; for even in lands of long-standing civilisation like our own, where conditions favour detailed and accurate observation, no biological controversies are more strenuous and more indeterminate than those relating to the economic values and the need for preservation or destruction of some of the commonest species. If that is so, how can it be hoped to plan rational laws in the outlying parts of the Empire, where sometimes the need of immediate action seems to be greatest, and where at the same time the balanced knowledge upon which action should be based is least available. Tentative legislation, the effects of which are closely watched and which may be modified at the shortest notice, is the experimental way; but a better way if time allows is to begin by making particular efforts to gather and collate all the information bearing upon the wild fauna in its own relations of numbers, distribution and multiplication, and in its relations to the various activities of humanity, native and non-native. The latter method, with its field surveys and statistics, is being increasingly employed, as every issue of the *Journal of the Society for the Preservation of the Fauna of the Empire* shows; it is exemplified on the best standard in a report just published by the Government of Northern Rhodesia*. The author is Capt. C. R. S. Pitman, game warden in Uganda, whose annual reports on the game of the Protectorate make one of the most interesting and valuable records of the wild life of Africa, and who carried out the Northern Rhodesia survey and investigations in 1931–32 under instructions received through the Secretary of State for the Colonies.

Since the conditions in Northern Rhodesia are fairly representative of conditions in many countries in process of colonisation, the report carries implications of more than local significance. The most general of these is that game, on the whole, has shown a marked decrease in recent years, and that this decrease is progressive, in spite of the fact that a few species have, during the same period, increased enormously in numbers. Natural agencies, as well as man, have contributed to the decrease. Capt. Pitman attributes it, in the first

* A Report on a Faunal Survey of Northern Rhodesia, with especial reference to Game, Elephant Control and National Parks. Pp. xii + 500 + xxxii + 11 maps. (Livingstone, N.R.: Government Printer; London: Crown Agents for the Colonies, 1935.) 7s. 6d. net.

place, to the great rinderpest epidemic of thirty to forty years ago, which over vast areas wiped out the ungulates, particularly buffalo, eland, lechwe, waterbuck, bushbuck, pig and warthog. Before the stock had had time wholly to recover, the Great War came along, and slaughter for the food of the forces again reduced it "practically to vanishing point" in certain of the provinces. From this disaster most of the species have never recovered, and in their reduced numbers incessant harrying by natives armed with muzzle-loading guns (of which nearly 25,000 have been registered by natives) has caused a progressive decline, and in many localities has brought species to that paucity of numbers which is the forerunner of extinction. Finally, the coming of the railway and the development of mining areas have led to the death of several hundred thousand herd at the hands of Europeans.

The general result is that from districts here and there in which they were once common, species are disappearing: where Broken Hill now stands was once one of the best hunting grounds for the greater kudu, the rhinoceros is all but gone from North-Eastern Rhodesia, the blue wildebeest has vanished from the Awemba district, the lechwe from Kawambwa, game generally from the Fort Rosebery District.

Nevertheless, Northern Rhodesia still remains a land well-stocked. An effort to estimate the numbers of game animals, even though it be regarded as only roughly approximate, is full of interest. Amongst the rarer forms are the giraffe (300 individuals), black-faced impala (500), rhinoceros (1,500), yellow-backed duiker (about 1,500), blue wildebeest (2,000), hippopotamus (3,000); while at the other end of the scale are species such as zebra (50,000), buffalo, roan antelope, Lichtenstein's hartebeest, common duiker (all with about 60,000 individuals), and, far and away the most abundant of all, the black and red lechwes (*Onotragus*) numbering 150,000 and 250,000 respectively. The last two species make up nearly half the total ungulate population of about one million, and this, equally distributed, would average about four individuals to the square mile, or approximately the density of the human population throughout the colony.

In this mass of varieties and of numbers, only some half dozen species appear to be able to stem the current of decline, and only three to make headway against it. The ability to withstand an almost universal tendency depends upon different factors in relation to these select animals and is of great significance from an ecological point of view. Thornicroft's giraffe and Cookson's wildebeest owe their present numbers to the co-operation of the local native authorities in protecting these last representatives of particular races, rather than to any natural power of resistance. The lechwe antelopes have been from time immemorial subjected to great slaughter intensified by a system of extensive driving. In spite of statements to the contrary, Capt. Pitman states that great drives still take place, but yet there is no sign of falling numbers, and this can be attributed only to the enormous annual increase of the lechwe herds. The tsessebe antelope (*Damaliscus lunatus*), curious in its distribution because in Barotse it is abundant on the right bank of the Zambezi and completely absent from the left, has not only been able to withstand the general influences, but has actually increased in numbers from hundreds to thousands in post-War days; and this would appear to be due, first, to its habit of keeping in small herds averaging 20–50 individuals, and secondly to a characteristic shyness (or wisdom) which keeps it well out of range of the muzzle-loaders of the natives.

The other two successful species, buffalo and elephant, have multiplied simply because they are large, dangerous animals, not easily tackled with muzzle-loaders. In a buffalo hunt in 1930 when, near the Kafue flats, a herd was driven, according to custom, into a selected swamp, the toll of dead was 30 buffalo and 7 of their native hunters. The amazing rapidity of the increase of this destructive species demands a planned effort at reducing their numbers and maintaining a constant check upon their increase. The same may be said about the elephant, of which there are at least 12,000 in Northern Rhodesia, and which are believed to have trebled in number during the past thirty years. Although there is no general excess, there are districts where the herds are rapidly becoming disturbingly large. The elephant must run no risk of extermination, but the cultivation and the works of man must also be considered. Based upon the rate of increase of the herds, which is estimated at 600 calves a year, Capt. Pitman suggests that control, exacting during the first three years up to a total of 800 individuals, could be organised in such a way that the herds of elephants at present roaming Northern Rhodesia would be shepherded into areas where there was the least chance of their interference with cultivation, and where their numbers could be kept at

the highest level consistent with the welfare of the human population. He is of opinion that, in spite of the low price of ivory (in April 1934 the local African price was 6*s*. 6*d*. per lb.), the control could be carried out by the Government with an excess of revenue over expenditure.

On the much debated question of the relationship between game and the survival of the tsetse fly, Capt. Pitman makes no pronouncement, but he notes that there is a tendency for this noxious carrier of sleeping-sickness (*Glossina morsitans*) to be carried from infected to fly-free areas by mechanical transport along the roads, and as regards game in the fly-belts themselves his conclusion is surely a sound one in the interests of both mankind and wild stock. "In a sparingly populated country like Northern Rhodesia, where 'fly' belts predominate, precluding the possibility of the natives keeping the necessary stock for their meat requirements, it is a duty to the indigenous population—in the absence of a 'fly' specific—to ensure the perpetuation of an adequate quantity of the wild animals from a dietetic point of view, if for no other; and to this end must native opinion be educated."

To strike a just balance between the various interests of mankind and the survival of wild game is no easy matter, and while regulations regarding game licences and the control of game in general, by protection or limited destruction, are essential and helpful, the safety of wild animals in the future is bound up with the establishment and efficient policing of game reserves and national sanctuaries in regions of sparse population, where the promise of native interference is slightest and of permanency greatest. J. R.

Back to Minkowski

Relativity:
an Elementary Explanation of the Space-Time Relations as established by Minkowski, and a Discussion of Gravitational Theory based thereon. By Dr. F. W. Lanchester. Pp. xiv+222. (London: Constable and Co., Ltd., 1935.) 12*s*. net.

DR. LANCHESTER, usually thought of in connexion with aerodynamics and motor engineering, has been interested in the theory of relativity since so far back as 1908, when he met Minkowski soon after the well-known pronouncement that "henceforth space by itself and time by itself will fade to mere shadows, and only a kind of union of the two will remain". The object of the present book is to reconstruct and develop the theory anew, following Minkowski rather than Einstein, and replacing advanced mathematical methods such as the tensor calculus by elementary geometry and algebra, illustrated by a large number of diagrams. On several topics, such as the velocity of light, space curvature, and the expansion of the universe, Dr. Lanchester differs from the usual conclusions.

Chapters i–iv, dealing with the restricted theory, call for little comment. In Chapter v it is argued that the phenomena of the pressure of light and the diffusion of matter by radiation compel us to reject the usual doctrine that the velocity of light in a vacuum is equal to the limiting velocity which can never be exceeded (that is, the *c* of the Lorentz formulae). Chapters vi–viii are described as an attempt to deal with gravitation on the basis of Minkowski's work. Planetary motion is treated by combining the Newtonian law of attraction with the FitzGerald contraction. The displacement of the Fraunhofer lines is deduced from the assumption that the time-rate of the 'solar chronometer' corresponds to that of an imaginary planet just skimming the sun's surface. This assumption gives half of Einstein's result. All that is claimed for this treatment of gravitation is that it gives results of the right kind and the right order of magnitude without making use of more than the most elementary algebraic expressions. It is acknowledged that space and time are dealt with separately, instead of together, and that the exposition lacks finality.

Chapters ix and x discuss some difficulties concerning the propagation of gravitation and the irregularities in the earth's rotation. In Chapter xii, the author disagrees with Einstein's principle of equivalence, which is considered as difficult to reconcile with the relativity theory of gravitation. It is suggested that the principle should be regarded as "no more than a scaffolding or temporary support, made use of by Einstein in the erection of his edifice, ultimately to be discarded". Chapters xi and xiii attack the theories of the expansion of the universe and general space-curvature. It is pointed out that

the apparent regression of the nebulae may be interpreted as a progressive diminution in the velocity of light. The author considers that "in the present state of knowledge he can find no reason or even excuse for postulating spherical space or any other of the imaginary forms proposed". Those who do so "are like those who in past times spent no less ingenuity in devising mechanical models of a hypothetical all-pervading medium which according to present-day philosophy has no existence". . . . "It may be that some day we shall wake, as from a dream, to find that things are not so different from what they seem after all."

The book concludes with twelve appendixes and an index. H. T. H. P.

(Leipzig: Akademische Verlagsgesellschaft m.b.H., 1932–1934.)

(1) IN a monograph of 637 pages Prof. C. Fr. Roewer has assembled the information available in the literature on the Solifuga and has revised and extended this in the light of his observations on more than 2,500 specimens. The diagnosis of the order, a very brief history and a list of nearly 400 papers on Solifuga precede the account of the organisation, in which the external features are described in great detail, including the remarkable organs termed malleoli, situated on the coxa and the two proximal trochanters of the fourth leg, the function of which is still undetermined. The description of the internal organs occupies about fifty pages and is followed by a short account of the embryonic and post-embryonic development and by an interesting chapter of fifteen pages on the biology of Solifuga.

More than half the work (350 pp.) is devoted to the systematics of the order, which is subdivided into ten families and 138 genera, many of which are new. The distribution of the families is shown on a series of outline maps. A discussion of the phylogeny concludes by quoting Kästner's summary that, if the ancestral arachnid were *Limulus*-like, the scorpion is the oldest arachnid, but if the arachnids arose in the Tracheata the Solifuga must be regarded as the most primitive. A diagram is given showing the relations of the families to the Rhagodidae—regarded as the most primitive family.

The order Palpigrada, the first representative of which was discovered by Grassi fifty years ago, contains small, even minute, forms which vary in length from 0·8 mm. to 2·8 mm. The bibliography on this order consists of only about thirty papers. The external characters and the internal anatomy, of which the principal features are fairly well known, are described, but the embryonic development has not been investigated and little is known of the post-embryonic growth. The food is believed to consist of the contents of the eggs of *Japyx*, *Campodea* and *Pauropus*. The order has only the one family (Kœneniidae) established by Grassi, which contains four genera and twenty species. The Palpigrada are regarded as standing with the Solifuga, at the base of the arachnid stem, and the former present a greater number of archaic characters.

The volume has a general and a systematic index, and is well provided with dichotomous keys and with illustrations in line to demonstrate the principal systematic and structural features.

(2) These three parts on the Rotifera conform in method of treatment and in excellence of illustration to the high standard of the first part (see NATURE, 129, 743; 1932). In the present parts the account of the anatomy of rotifers is completed

and particular attention may be directed to the sections on the alimentary canal including the mastax, on the muscles, with some useful schematic figures, on the protonephridia and on the reproductive organs. The development is carefully considered. The classification used is a modification of that proposed in 1899 by Wesenberg-Lund; there are three orders—Seisonidea, Bdelloidea and Monogononta, the last of which is divided into three suborders—Ploima, Floscullariacea and Collothecacea. The systematic consideration of the genera follows. We look forward to the completion of this well-balanced account of an unusually interesting group of animals.

(3) The fourth part of the work on the Bivalvia is devoted to the further consideration of the shell and of pearls. The methods for distinguishing ordinary and culture pearls are described; for example, by examination under different forms of illumination and in a magnetic field, by their specific gravities and by investigation of the nucleus after boring halfway through the pearl. An interesting historical account of the culture of pearls follows. The author then proceeds to the description of the changes of the form of the shell during growth, the effect of the three-dimensional growth on the closing mechanism and the influence of varying conditions on shell-form, that is, the plasticity of the shell. A useful account is given of the variations in dimensions, weight, sculpture and periostracum of the shell and of the convergence in shell-form in different genera; for example, the shell-form characteristic of *Mytilus* is found in other genera, as in certain *Tridacna* and in *Driessena*. The work concludes with an additional list of nearly 900 titles of works on bivalves.

(4) The first part of the new volume on Opisthobranchia, with the exception of a definition, a concise statement of the principal external and internal features and an outline of the classification, is devoted to a bibliography extending to 150 pages and containing references to more than 3,000 works on this order of molluscs.

Gaza

Ancient Gaza, 4: Tell el Ajjūl

By Sir Flinders Petrie. Pp. vii+21+70 plates. (London: British School of Archæology in Egypt; Bernard Quaritch, Ltd., 1934.) 50*s*.

IN this volume Sir Flinders Petrie, following his usual and admirable practice of publishing the report on his work in the field with a minimum of delay, has given subscribers to the British School of Archæology in Egypt and archæologists in general a fully illustrated account of the material obtained by the expedition to Gaza (Tell el Ajjūl) in 1933–34. This season, the fourth spent on that site, was devoted to clearing about five acres of the Tell down to native rock, further work on the cemetery, and to drawing objects and preparing plans.

The area selected for excavation presented unexpected difficulties. Not only was it found to have suffered much from denudation, but also it had been used as a cemetery in the Hyksos period and for later burials. Further, the old land surface had been deeply cut by denudation before settlement began. Dating proved a complex matter, and so shallow were the deposits and in such separate patches that no continuity of stratification could be fixed. Dating by pottery, therefore, had to serve in linking up the area with palace levels. The most continuous course of stone basing of the walls is to be accepted as "representing the kind of civilization acquired during the xvth dynasty rule in Egypt".

What is perhaps the most remarkable feature of the season's results is the quantity of jewellery—gold, silver or electrum—recovered, not only in graves, but also in three hoards, evidently from their character old metal intended for melting up, which reflects the wanderings of a Syrian metal trader.

Two hundred and twenty weights were recorded, of which one third were surface finds. These bring the total of weights found at Gaza up to 448. The standards represented are Palestine, Babylonia, the West, Egypt, Syria, Persia, Phœnicia and an international gold beqa. The percentages of the standards indicate that Syria, with Persia and Babylonia, were far more influential in trade than Egypt. The small size of the weights is also remarkable.

Sir Flinders concludes his report with some general reflections evoked by the conclusion of his activities at Ajjūl owing to the change in the conditions of excavation imposed by the Antiquities Department. In consequence, the work of the School has now been transferred to Syria. In summarising the work that has been accomplished in eight seasons, he points out that these years have been more fruitful for the history of Egypt than any he has spent in the field, with the exception of those of the Naqada and Badari discoveries. Two dark ages of Egypt have been

explained by the invasion of people from the Caspian basin—the highly developed rock-workers of the seventh and eighth dynasties and the rude horsemen of the fifteenth and sixteenth dynasties. In the history of Palestine, instead of vague bronze and iron ages, dating has now been stabilised by scales of Egyptian dating and earlier sequence dates.

Further, it is pointed out, Gaza has revealed the more advanced work of a higher civilisation which was imported from foreign lands lying to the north. It has now become one of the problems of archæology in the Nearer East to investigate this unknown civilisation. The jewellery, of forms without parallel, imported to Gaza before 2000 B.C., invites further research. So Sir Flinders with indomitable spirit takes up the challenge and transfers his activities to Syria in the hope that he may be the pioneer in discovery here, as he has been elsewhere, and bring to light the origin of these previously unknown forms in what, he hopes, may prove to be the greatest culture of those ages.

Progress in Enzyme Study

Ergebnisse der Enzymforschung

Herausgegeben von F. F. Nord und R. Weidenhagen. Band 4. Pp. xii+391. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1935.) 31 gold marks.

THE subjects chosen for critical discussion in this, the fourth annual issue of 'enzyme progress', relate to more difficult and obscure sections of the field: it is perhaps all the more valuable to have them monographed.

As before, the contributors are from laboratories in many countries, and the contributions in three languages. T. Bersin of Marburg writes on thio-compounds and enzymes, to which attention has been particularly directed as the result of the work on the tripeptide, glutathione, which has the grouping $-CH_2SH$ in a side-chain, and takes part in a reversible biological oxidation-reduction system. There is evidence that the ferment papain is only active when it contains an SH group, and the same is true of urease. The relation of glutathione to the activity of several other enzymes is discussed.

That activation and inhibition of certain enzymes is brought about by definite chemical compounds is well known. In particular, activity is affected by hydrogen ion concentration; oxidation-reduction potentials also seem to play a part. The existing knowledge of this subject for a number of specific enzymes is summarised by H. Tauber of New York.

The discussion as to the intermediate stages during the biological degradation of sugar is continued by O. Meyerhof of Heidelberg in regard to the formation both of lactic acid and alcohol respectively as end products. In both cases, sugar phosphoric acids appear in the early stages: the scheme of Embden seems to be finding general acceptance.

Information of a more exact character is accumulating in regard to the fermentation of the sugars by various bacteria which leads, in certain examples, to such products as propionic or butyric acids, to butyl alcohol or to methane. This section is written by A. J. Kluyver of Delft, who has managed to condense a good deal of information into some forty pages.

Somewhat novel is a contribution from Hungary by Bodmár and Barta on the enzymes of the tobacco leaf and the biochemical changes during the drying and fermentation of tobacco. This is essentially an operation which should be under biochemical control, and its fuller understanding will undoubtedly be of interest to what is largely an empirical industry.

A second section of industrial application is that by Albert Hesse of Munich on enzymes in the bakery, in which the newer work is elaborated. The differences in the wheat flours of the various countries and the variations in the national requirements in regard to the nature of the loaf make international comparisons and deductions in this subject impossible. Baking is another example of an industry which is still largely empirical, and so has much to learn from biochemical science.

The only section in French is by Maurice Beau of Paris; it deals with rennet and the coagulation of milk. Considering its importance, milk has been much neglected by the biochemist, and there is all to learn about its proteins and minor components. The work is, of course, of extreme difficulty both experimentally and in regard to its interpretation. One phase of it, that of lactoflavin—which is possibly vitamin B_2—is elaborated here by Wagner-Jauregg of Heidelberg, who has been associated with Kuhn in much of his most brilliant work in this subject. This has enabled both the determination of the constitution of

lactoflavin and the synthesis of what is probably a stereoisomeric colouring matter from *l*-arabinose.

The final section, contributed from Princeton by E. Newton Harvey, deals with a novel subject, namely luciferase, which is an enzyme concerned in the luminescence of living organisms.

The editors and authors are once more to be congratulated on the production of a volume which will be found both stimulating and helpful to all workers in these particular fields of inquiry.

E. F. A.

An Introduction to Structural Theory and Design: Theory

By Prof. H. Sutherland and Prof. H. L. Bowman. Second edition. Pp. xi+318. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935.) 17*s.* 6*d.* net.

SINCE its original publication about five years ago, this work has proved itself a very valuable introduction to the basic conceptions and principles of structural theory as related to trusses, rigid frames and space frameworks, and has asserted itself as a trustworthy book of reference. In preparing the second edition, the authors have taken this opportunity to effect some revision, particularly in enlarging the section on moment distribution and in adding one on the column analogy for rigid frame analysis.

On the whole, however, the book follows the same lines as its predecessor in treating, very conscientiously and with a wise insistence on the value of simple proofs and direct solutions, the stress analysis of the wide range of structures included in its purview. It is particularly rich in the explanations given of the numerous direct and indirect methods of analysis which are available and, while its purpose is to interpret as fully as possible the introductory theory of structures, this is illustrated by numerous worked examples showing how, in practice, the actual processes, be they graphical or analytical, are carried out. With the many further problems suggested for analysis, the work could be used to great advantage for class or private study. At the same time, the clear-cut subdivision of the matter, the finality with which each method is treated and the practical outlook of the authors make it within its limits an eminently useful book for those professionally engaged in structural work.

J. A. C.

Electrical Water Heating: with Special Reference to the Domestic Storage Heater

By D. J. Bolton, Philip C. Honey and N. S. Richardson. Pp. viii+192. (London: Chapman and Hall, Ltd., 1935.) 7*s.* 6*d.* net.

THIS book deals with both the scientific and the commercial aspects of electrical water heating. It naturally falls into three main divisions: the first one is concerned with the construction of domestic storage heaters of various types, and the method of fixing and fitting them in the house; the second with the hot water systems at present in ordinary domestic use; and the last with the supply and consumption of electricity commercially.

There is a good description of the control of the temperature of electric heaters by the bi-metallic type of thermostat. In this, the differential expansion of invar and brass is employed to give the necessary change of length, and the method of enclosing such thermo-regulators in the cylindrical water-storage tanks is discussed in considerable detail. Various methods of grafting such an electrical system on to the existing hot-water circuit of the house are also included, and the several factors which affect the price of electricity as sold to the consumer are set out clearly. This book should prove of service to electrical engineers who are concerned with the problem of water heating, as well as to architects who are preparing to design the houses of the future.

Die Harze:

die botanischen und chemischen Grundlagen unserer Kenntnisse über die Bildung, die Entwicklung und die Zusammensetzung der pflanzlichen Exkrete. Bearbeitet von A. Tschirch und Erich Stock. Dritte umgearbeitete Auflage von A. Tschirch: Die Harze und die Harzbehälter, Band 2, Hälfte 1. Pp. xii+471. (Berlin: Gebrüder Borntraeger, 1935.) 48 gold marks.

WE have already noticed (March 31, 1934, p. 478) the first portion of this monumental work, which dealt in general with the resins. There has now been issued the first half of the special part describing in detail the individual resins. Those chosen are classified as the ester or benzoic resins, commonly termed balsams, and the bitter resins such as myrrh, elemi, etc. The information, covering a very great deal besides botany and chemistry, is of the fullest, and there are copious illustrations, both botanical and otherwise, including pictures of the original packages in which the resins are shipped as well as maps. We know of no other similar subject which has been monographed so exhaustively.

Der Chemie-Ingenieur:

ein Handbuch der physikalischen Arbeitsmethoden in chemischen und verwandten Industriebetrieben. Herausgegeben von A. Eucken und M. Jakob. Generalregister für Band 1–2. Pp. ii+99. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1935.) 8.80 gold marks.

THIS small volume, which is uniform in type and binding with the eight parts of "Der Chemie Ingenieur", consists of a general classification of the subjects treated in these books and provides a rapid means of discovering in which part a particular detail of the general subject is discussed. It thus prevents one having to examine the tables of contents at the end of each part until that part in which is the particular section of the subject required is found. The general index will therefore greatly facilitate reference to the contents of these eight books, and the authors are to be congratulated on completing their labours in such a thorough manner.

Polymerisation and Condensation Reactions

AT the meeting of the Faraday Society held on September 26–28 at Cambridge under the presidency of Mr. W. Rintoul, the subject of polymerisation and condensation reactions was discussed.

The technical development of the manufacture of the group of substances known as plastics, resins and moulding powders is now attaining large dimensions, and it occurred to the Colloid Committee of the Faraday Society that academic interest in these substances might be stimulated by such a meeting. In this it was not mistaken. Whilst the Faraday discussions have always been somewhat international in character, this meeting was favoured by the attendance of an unusual number of both members and visitors who came from overseas.

We are indebted in the first instance to Staudinger for emphasising the now generally accepted view that the polymers and condensates must be regarded as constituted of macromolecules formed by the polymerisation or condensation of single units. Both the physical and chemical properties of the finished materials should be capable of interpretation on this basis.

We now recognise three different types of macromolecules: the linear, which can be written $A(A)_nA$ or $(AB)_n$; the large ring or closed type; and the cross-linked variety. This latter in its simplest form might be regarded as a system of linear macromolecules linked together by cross-linkages like the rungs on a ladder, and in its most complex state as a crystal like silica.

Amongst a number of important and interesting topics three attracted most attention: the mechanism of growth of the large molecules from the small ones; the information yielded by X-ray examination of the substances, especially when stressed; and the relationship between the mechanical and physical properties on one hand, and on the other the chemical structure of the material.

The discussion made it clear that there must be a number of different mechanisms by which macromolecules can be formed. For example, in the formation of a macromolecular ester from a dibasic acid and a dihydric alcohol, the chemical reaction involved, namely, the esterification process, would appear to be energetically identical both for commencing and for propagation of the chain. On the other hand, in the polymerisation of a substance like styrene, the energetics of commencement and propagation are widely different. Once the growth has been initiated by the formation of what may be termed, to borrow from the nomenclature of chain reactions, a reaction centre, the chain propagation proceeds relatively rapidly.

During the course of the meeting, it became clear that a number of new factors not operative in the ordinary gaseous chain reaction must be considered in the growth of the macromolecule. For example, it is evident that in different systems the length of the macromolecule is subject to wide variation. In the case of many olefine polymerisation processes the mean length of the macromolecule corresponds to the dimer; in the case of the acrylic acid the length can certainly exceed ten thousand of the monomeric units. At present, it is difficult to elucidate the reason for this wide variation in chain length. It seems possible, at least in the olefines, that ring closure to form a cyclic compound, which can, of course, open again, plays an important part in retarding the growth of the chain. In the drying oils a steric factor appears to be important; the polymer must thus be regarded in its undistorted form as spherical rather than thread-like. Both in the polymerisation of acetylene and in the case of formaldehyde, it seems certain that chain termination is brought about by a special type of collision of the growing end of the chain with a monomer, the terminating collision differing from the propagating collision both in the energy and the number of degrees of freedom involved.

One interesting feature of many of these reactions is the relatively rapid growth of the chain after initiation. It seems unlikely that this can take place through the ordinary collision mechanism, for the rate of diffusion of the monomer to the active centre at the end of the growing chain would then govern the reaction velocity; the energy of activation of the controlling process is known to be low, of the order of 5 kgm. cal. The suggestion was advanced that monomeric molecules might be supplied to the growing end of the chain by travelling along the chain. On this view, the process of chain growth must be regarded as analogous to the growth of crystals such as hydroquinone, where diffusion over the crystal surface plays a large part in controlling the rate of reaction.

Finally, it is well known that a macromolecule such as polystyrene can be decomposed into simple units by heat, and indeed at relatively low temperatures; the same appears to be true for

the polymeric forms of formaldehyde, but many similar polymers are not so readily reversibly decomposed and require really high temperatures to bring about thermal destruction, from the products of which the monomer can be isolated. It is significant in this connexion that the pyrolysis of straight chain hydrocarbons proceeds more readily the longer the chain.

The chain-like structure of the cellobiose polymer cellulose and the more complicated polypeptide chain found in the proteins has been confirmed in a satisfactory manner by X-ray examination. These systems are, of course, quite distinct from the ordinary crystal in that the series of parallel chains along which the composition and structure are subject to repetition are usually so long that it is impossible to identify the relatively small elementary cell as determined by X-ray examination with a definite number of macromolecules. The molecules are much longer than the elementary cell and the X-ray pattern obtained is a fibre diagram.

A number of polymers like the polyoxymethylenes exhibit a crystalline pattern; others like the phenol formaldehyde complexes only give an amorphous pattern; whilst a third and most interesting group give an amorphous pattern in their natural state but a crystalline pattern when stretched, these including rubber, polyvinyl alcohol, sulphur and polyethylene tetrasulphide. All these substances when stretched exhibit over a suitable range of temperature the remarkable extensibility shown by natural rubber. It is difficult to avoid the conclusion that great extensibility is associated with very long macromolecules, which are sufficiently flexible and at the same time mobile under stress to permit of orientation in parallel threads by the simple application of tension.

There are obvious difficulties to be overcome if this simple hypothesis be accepted as correct. On stretching rubber and freezing it, its fibre diagram and extension are both preserved; on warming, both extension and fibre diagram disappear, a process analogous to the melting of a solid. In a collection of small rod-shaped molecules in the liquid form, thermal agitation will ensure that the molecules are in complete disorder; but as the molecules grow longer the Van der Waals' forces of cohesion increase and the tendency for bundles or clusters of molecules to be formed with a common axis of orientation increases, a phenomenon termed cybotaxis. We might have anticipated unstretched rubber to be a cybotactic fluid *par excellence*. It is possible that this is really the case, but that the microclusters which are themselves in disorder are too small to be revealed by the X-rays. The thermal changes associated with the stretching of rubber give us a measure of the heat of adsorption of the polyprene chains on a polyprene surface.

The most important property of macromolecular polymers is that they alone amongst organic materials manifest to a significant degree such mechanical properties as strength, elasticity, toughness, pliability and hardness. Well oriented and fibrous polymers such as natural cellulose and silk are, weight for weight, stronger than iron. Synthetic polymers are not so strong as these natural products, and a good deal of attention has naturally been devoted to the problem of calculating the maximum tensile strength possible in a polymeric material and the cause of the relatively low values obtained. The following figures for the tensile strength in kgm. mm.$^{-2}$ for various materials at 20° C. are interesting:

Best spring steel	197	Iron	20
Flax	100	Glass	5
Rubber	80	Polystyrene	4
Silk	35	Urea formaldehyde	3
Wool	28	Asphalt	1×10^{-2}
Artificial silk	25		

Calculations from the form of the Morse potential curve show that a tensile strength of no less than 2,000 kgm./mm.^{2} would be obtained for a completely orientated and fibrous rod composed of a bundle of macromolecules the individual lengths of which are equal to that of the rod. There seems little reason to doubt that materials stronger than the best steel should be capable of being made.

Another interesting property peculiar to these polymers is their extensibility or swelling in various solvents. Linear or chain-like polymers may be prepared which undergo simple solution in appropriate solvents.

As the chain length of the macromolecules increases, the process of molecular solution commences due to solvent imbition and swelling of the solid; this is followed by the formation of aggregates or micelles. These micelles are eventually dispersed to the molecular form on further appropriate dilution of the solution. On the other hand, cross-linked polymers such as silica or vulcanised rubber or phenol formaldehyde resins do not swell or disperse in solvents.

Staudinger has prepared a most interesting series of products from polystyrene, exhibiting all the transition stages. Polystyrene consists of simple thread-like macromolecules which will go into true solution in organic solvents; the process of solution as we have noted being preceded by solvent imbition and swelling. If, however, to the styrene a small quantity of *p*-divinylbenzene be added before polymerisation, then when the chains are formed molecules of this material are incorporated in the growing chain and cross-

linkages come into existence by the formation of divinylbenzene bridges. Such a cross-linked system is no longer dispersible in solvents, although if not too many cross-linkages are formed the material is capable of swelling. If the ratio of styrene to divinylbenzene is as high as 50,000 to 1, the product is highly extensible but insoluble, whilst if it be as low as 1,000 to 1 the product shows scarcely any sign of swelling at all.

It is clear that the properties of the polymers and condensation products may be altered to a most extraordinary extent by the addition of suitable materials even in subanalytical amounts.

ERIC K. RIDEAL.

Maintenance of Life in Isolated Animal Organs

THE preliminary announcement of the work of Carrel and Lindberg on the maintenance of life in isolated organs, to which reference has already been made in our columns[1], can now be amplified with further details of their method, from which an idea can be obtained of how the difficulties involved have been surmounted[2]. The organs are removed with complete aseptic and antiseptic precautions from an animal that has just been killed by bleeding under anæsthesia; adult cats or fowls are generally used. With the organ are removed the surrounding tissues, arteries, veins, nerves and lymph vessels: for example, in the case of the ovary, with the organ itself are removed the Fallopian tube, and a flap of peritoneum and connective tissue containing the ovarian artery. During the operation the abdominal cavity and the organ are protected with gauze pads soaked in Dakin's solution.

The organ is introduced into the culture chamber protected by a sheet of 'cellophane' and the artery is connected with the cannula of the apparatus; the chamber is closed by a rubber stopper and sealed with a cellulose acetate cement. A sterile pulsating circulation is maintained through the organ by the apparatus; different culture media have been used for this purpose. In order that the supply of glucose and bicarbonate may be sufficient for several days, the volume of the medium must be about 2,000 times greater than that of the tissues. For example, a cat's thyroid which weighs 85–110 mgm. requires about 230 c.c. of fluid. The apparatus may be used with 200–900 c.c. of medium. The latter may be blood-serum, diluted with Tyrode's solution, and containing sometimes hæmoglobin, or an artificial growth-activating solution, containing protein-split products, hæmin, cysteine, insulin, thyroxine, glutathione, vitamins A and C, blood-serum, etc. A small amount of phenol red must be added, as indicator of the metabolic activity of the organ, as well as of the occurrence of bacterial infection. The medium is under an atmosphere of 40 per cent oxygen and 3–4 per cent carbon dioxide, the remainder being nitrogen, and is kept well aerated.

The apparatus is kept in an incubator at 37°–38° C. and is so designed that the organ and perfusion fluid can be continuously observed. The circulation is started about an hour after the death of the animal; the number of pulsations is usually about 60 per minute, the systolic pressure being 120 mm. mercury and the diastolic 60 mm. mercury. Rate and pressure can be varied at will.

The organs used in the apparatus so far have been the thyroid gland, the ovary, the suprarenal gland, the spleen, heart and kidney. In the case of the thyroid, three different media have been used as perfusion fluids; with diluted serum or an artificial medium containing amino-acids, the volume of the gland decreased and the follicles remained full of colloid, even after twenty-one days. With the medium containing peptones the glands grew and doubled their weight in three to four days; the consumption of sugar was increased more than three times. Histologically, there were observed either a disordered epithelial proliferation with disappearance of the colloid or an increase in the volume of the cells and in the number of follicles, with production of colloid. In an experiment with an ovary perfused with a growth-promoting medium, the weight of the organ increased from 90 mgm. to 284 mgm. in five days and three corpora lutea developed. Growth was, however, accompanied by disorganisation; there was a luxuriant and disordered proliferation of the stroma and of the epithelial cells.

These experiments show that an entire organ can be kept alive *in vitro*, increasing in size and weight, due to the appearance of new cells and tissues. The method should have great value in the study of different organs, especially those having an 'internal secretion', and further reports by Carrel and Lindberg will be awaited with interest. If it is permissible to speculate about the future, will it be possible for the chemist to utilise isolated perfused organs for the manufacture of their specific secretions in unlimited quantities, in cases in which a chemical synthesis is difficult or has not yet been achieved?

Recent Antarctic Research

undertaken by the Discovery Committee

THE R.R.S. *Discovery II*, 1933-35

By Dr. N. A. Mackintosh

THE R.R.S. *Discovery II* returned to England at the end of her third commission in June this year. During the twenty months she was away, her work included an examination of the whale population and its environment in the vicinity of the Atlantic and Pacific ice edge; repeated observations on a particular meridian for the study of seasonal variations; some repetition and consolidation of observations taken in previous commissions; a survey of the South Shetland Islands and, on the homeward voyage, a new line of stations running parallel to the East African coast from Marion Island in 47° S. to the Gulf of Aden. Throughout the commission, routine soundings were taken with the echo-sounding machines. The route taken by the ship on her various cruises is indicated in Fig. 1.

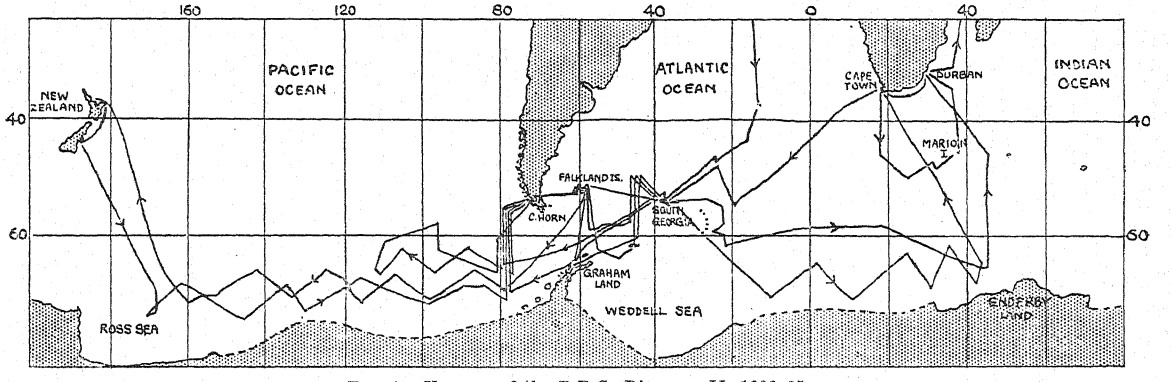

FIG. 1. Voyages of the R.R.S. *Discovery II*, 1933-35.

Several years will, of course, be required for a proper examination of the material and data collected, but certain interesting points have already arisen and may be briefly described here.

During several long cruises, in which a zigzag course was followed to the north of the pack ice, direct and continuous observations on whales were combined with routine observations on plankton and hydrology. These observations provide material for comparing the abundance of whales in the Pacific and Atlantic sectors of the Antarctic, and an important correlation has been observed between the distribution of whales and the surface temperature of the water. It is anticipated that the most important results of the commission's work will in due course be derived from these cruises off the ice edge.

The section of the work which may be said to have yielded the quickest results was that in which a line of stations on the meridian of 80° W. was repeated in December, March, September, October and November. Each line included from seven to ten stations at intervals of about 90 miles, and in each case the southernmost station was at the edge of the pack ice. The routine at each station included a series of six vertical hauls with closing 70-cm. plankton nets from various depths between 1,000 metres and the surface. A preliminary examination of the samples from these nets reveals a large-scale migration of the plankton which is likely to be of far-reaching importance.

It is known that in the Antarctic zone there is a thin layer of cold Antarctic surface water which moves with a northerly component away from the ice. Below this is the so-called warm deep water flowing south, and below this again the cold Antarctic bottom water which moves northwards. Fig. 2 shows six vertical sections of the line in 80° W. The first shows diagrammatically the circulation of the surface water and the warm deep water. The other five show the newly ascertained distribution of the copepod *Rhincalanus gigas* in the various months in which the line was repeated. They are drawn quite roughly and may need adjustment when the material is examined in more detail. In December (summer) the species is mainly concentrated near the surface. In March it tends to sink to the north of the Antarctic convergence. In September (winter) it is practically confined to the warm deep water, and in October and November (spring) it has largely regained the Antarctic surface water. Similar seasonal changes in level have been

observed in several other species which, together with *R. gigas*, make up the bulk of the Antarctic macroplankton, but these do not appear to include the Crustacean, *Euphausia superba*, which constitutes the food of the Blue and Fin whales. To those who have studied the plankton of the Southern Ocean, it has for long been a problem to understand how organisms drifting in the surface water are not all carried northward into warmer latitudes where they could not be expected to survive. The stations worked by the *Discovery II* in 80° W. have provided material

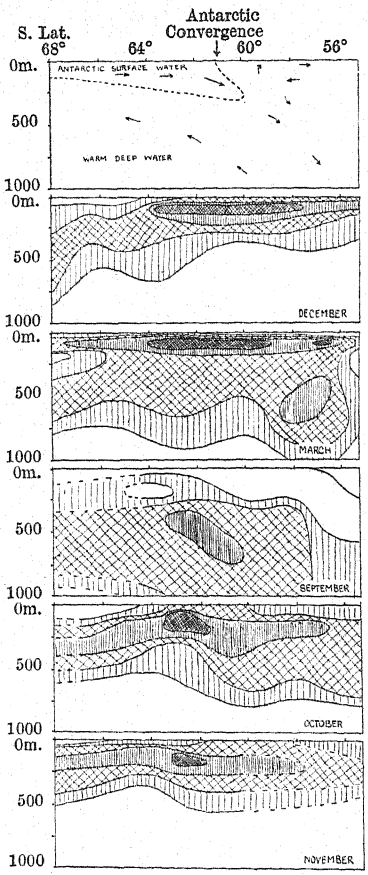

FIG. 2. Seasonal changes in the vertical distribution of the Copepod *Rhincalanus gigas* on the meridian of 80° W.

from the consideration of which a very substantial contribution can be made towards the solution of this problem. It appears certain that at least a considerable number of the species are carried northwards in summer in the north-flowing surface water, and return south again in winter in the southgoing stream at depths of at least 400 m. It is believed that such a large-scale circulation of the plankton, extending over some hundreds of miles of latitude, has not hitherto been demonstrated in any part of the world.

Among the new devices which were successfully used during this commission mention may be made of the Harvey phytoplankton net and the echo-sounding recorder. The former is an apparatus designed by Mr. F. W. Harvey of Plymouth[1]. Samples of phytoplankton are treated with acetone, and the amount of chlorophyll extracted is measured by comparison with a series of colour standards. This method is a great improvement on any hitherto used for estimating the relative abundance of phytoplankton in different localities. The apparatus was used at almost every station throughout the commission. With the echo-sounding recorder, the echo from the sea floor, produced by the ordinary deep-sea hammer, is picked up by a microphone and automatically marked on a moving scroll of paper. On this the contour of the bottom is traced out as a continuous line. It is most effective in shallow water and in places where rapid changes in depth occur, and it was in continual use during the surveying of the South Shetland Islands.

Among oceanic soundings, perhaps the most interesting observations were those made in the South Sandwich Deep. Soundings of 7,000–8,000 metres had previously been obtained to the east and north-east of the South Sandwich Islands. It has now been shown that the deep extends considerably farther south in the form of a curious narrow cleft in the sea floor exceeding 7,000 metres in depth, and running parallel with the chain of islands and the bend of the Scotia arc.

On the long line of stations taken up the East African coast, the fullest hydrological observations were made. The vertical section of this line is most instructive, and throws much light on the major current systems of the Indian Ocean. Large closing nets fished in deep water on the same line produced abundant material of biological interest.

During this commission the ship was under the executive command of Lieut. A. L. Nelson, R.N.R.

THE R.R.S. *William Scoresby*, 1934-35

By G. W. Rayner

The Discovery Committee's vessel, the R.R.S. *William Scoresby*, completed in May this year her fourth commission—a short one of seven months devoted entirely to the marking of whales on the whaling grounds in the Antarctic seas off Queen Mary Land, off Enderby Land and to the south of Bouvet Island. The ship sailed from London on October 16, 1934, and made a direct passage to Simonstown, where final preparations for the work in hand were completed. The ship's personnel, under the executive command of Lieut.-Comdr. C. R. U. Boothby, R.N.R., included an experienced Norwegian whale gunner, Capt. J. Endresen, who had charge of the manœuvring of the vessel whilst

hunting and marking whales. The pack ice was encountered on December 3 when seven days out from Cape Town. Whales had been found on December 1 and marking began on that date.

The R.R.S. *William Scoresby* is an oil-burning steam vessel, and arrangements had been made for supplies of fuel oil from the whaling factory ships operating in the neighbourhood. On reaching the pack ice the vessel turned eastwards along its edge, and a few days later ships of the whaling fleet were heard in wireless communication with each other. When fuel oil was required, the vessel was enabled to find the desired factory ship by wireless bearings. She went alongside the factory ships in the same manner as the catchers go alongside for fuel—that is, with a floating whale carcase between the two ships to act as a fender. This manœuvre was carried out, in the open ocean, on eight occasions.

At the beginning of the season, the majority of the whaling fleet was found to be operating in the neighbourhood of Queen Mary Land, and marking was carried out in this area until the middle of January. During this period, which was largely spent near the edge of the pack ice or inside it, the work was hampered by poor visibility, much snow and fog, but on several occasions when the weather was good, numbers of Humpback and Fin whales were met and marked. Half way through January, a return westwards to the whaling grounds of Enderby Land was made, again skirting the pack ice which was now lying considerably farther south. Off Enderby Land, work was carried on in the open ocean and the pack ice was not again encountered during the remainder of the season. From this time until almost the end of the season, the weather was good and both Blue and Fin whales were usually to be found, sometimes in large numbers. Fin whales are to be met with at this time of the year in bodies numbering as many as fifty to a hundred and, on occasions, two such bodies were found in the course of a single day. When this occurred it was possible to mark between forty and fifty in the long daylight hours.

One month was spent in the waters off Enderby Land, and in March the ship moved westwards to the south of Bouvet Island. In the middle of March course was laid for the Cape, which was reached on March 29 after 122 days at sea without sighting land of any kind. During this time between seven and eight hundred whales—Blue, Fin, Humpback and Sperm—had been marked.

When opportunity offered, during bad weather or dark hours, water and plankton samples were taken and, for a few days in February, when in wireless communication with the R.R.S. *Discovery II*, the *William Scoresby* was able to co-operate to a small extent in her programme of hydrographic and plankton research.

In the months of December and January of this season, whale-marking was also carried out in the waters around South Georgia by Mr. A. H. Laurie, and several hundred Fin and Blue whales were marked in this area.

A number of whales marked during this commission have already been captured by the whalers, and the marks, together with the required data, returned to the Discovery Committee. Marks from Blue, Fin and Humpback whales have thus been recovered after periods varying from a few hours to three and a half months; and the distances traversed range from a few miles to a thousand miles. The data thus obtained are extremely instructive in showing the trend of movement of the whale stock on these grounds during the course of the season, but more valuable results are to be expected from marks returned during next whaling season.

National Food Policy

BRITISH ASSOCIATION DISCUSSION ON ECONOMICS OF DIET

THE discussion on the economics of diet before Sections F and I (Economics and Physiology) at the recent Norwich meeting of the British Association, and the resolution on nutrition at the present assembly of the League of Nations has emphasised the interdependence of problems of public health, agriculture and economics. This interdependence has become evident in the last few years of trade depression when attempts, which are not very successful, are being made to deal with the problems of these subjects separately. It is now being realised that they must be considered together in the light of the international position.

The world economic crisis paralysed international trade in foodstuffs as well as in other commodities. But agricultural production cannot be cut down so quickly as industrial factory production. Consequently stores of foodstuffs accumulated and prices fell.

The first reaction was an attempt to control production, limit imports and regulate marketing

with the object of raising prices. It was thought that when wholesale prices of foodstuffs rose, the purchasing power of primary producers for industrial commodities would be increased and general prosperity would return with an all-round rise in prices.

A different view is that low prices for agricultural products are the result rather than the cause of trade depression. Under-consumption, due to low purchasing power of the people in the industrial centres where depression is worse than in agriculture, is a more potent factor than over-production. Hence raising prices by reducing production and regulating the markets will lead to a further lowering of consumption, with the 'glut' appearing at a still lower level of consumption, a still further restriction in trade, and in addition, an increase in malnutrition due to a worsening of the diet of the poorer classes of the community. Those who approach the problem from this angle wish to find a solution of our problems in increased consumption rather than in controlled production.

The crux of the difficulty is how to initiate the desired increased consumption. One of the speakers at the British Association suggested that a beginning should be made with food. The present Agricultural Marketing Boards should be replaced by public utility companies which would run the processing centres; for example, centralised slaughter-houses, bacon factories, wholesale milk depots, through which products must pass from the farm to the consumer. These Boards would buy from the farmer and sell to the distributing trade. The gulf between what the farmer would get and what the consumer is asked to pay would be bridged by a direct subsidy from the State, paid to these Boards.

There would be no control of retail prices, because the services of distribution vary so widely in different classes. But the Boards, either themselves or by arrangement with distributors, would make the staple foodstuffs available at a price within the reach of the poorest. They would be available without tickets and irrespective of class, to all who would be willing to collect food from the depots or shops, and so save the cost of distribution which, in the case of some foodstuffs, for example, milk, is about half the retail price.

With the subsidy and this saving in the cost of distribution for those who care to take advantage of it, a diet adequate for health would be within the reach of the poorest. It was suggested that the result would be a reduction in preventible disease which, within a reasonable time, would effect savings in the cost of public health services which would go far to offset the cost of subsidising increased consumption. In addition to ultimate savings arising from improvement in health, there would be an immediate saving in the cost of complicated public health measures such as free meals and cheap milk for school children, and the issue of dried milk free or at reduced prices at child welfare centres. These measures with their taint of pauperism would be no longer necessary.

The results of a preliminary inquiry seemed to indicate that there may be as many as twenty million of the population whose health would be improved by an increased consumption of the more expensive foodstuffs such as fruit, vegetables, milk and animal products, and an examination of family food budgets and family incomes showed that price was the limiting factor for the consumption of these. If consumption were increased to a level at which every member of the community had a diet adequate for health, there would be room for a considerable expansion of agriculture in Great Britain without decreasing imports.

To initiate a national food policy on these lines, however, requires a Government subsidy, and subsidies are unpopular. It is argued, however, that the subsidy, in addition to making agriculture remunerative, would irrigate the field of internal trade, stimulate industries, and flow back again to the Treasury in increased income tax and other receipts.

On the same day as the discussion at Norwich, twelve countries, including Great Britain, France and Italy, submitted to the Assembly of the League of Nations a resolution stating that "the relationship of nutrition to the health of the people has become a social and economic problem of widely accepted significance", and that "this subject has an important bearing on world agricultural problems". The League has approved an inquiry into the whole question.

The discussion at the British Association and at the League of Nations has aroused sufficient interest to ensure that there will be a fuller inquiry. It is probable that we may be working towards a national food policy into which both agriculture and public health interests can be fitted and reconciled. But as one of the speakers at the British Association urged, we need far more information than is available before a food policy can be elaborated. It is in the public interest that such an inquiry should be instituted to ascertain:

What is the amount of increased consumption required to provide an adequate diet for every member of the community?

To what extent can health be improved by increased consumption of certain foodstuffs?

What effect would increased consumption have on British agriculture and on trade ?

What economic and financial measures are required to initiate and promote increased consumption ?

There is obviously a wide field of inquiry in which different Government departments should co-operate. A halt should be called to planning according to preconceived theories. We need far more information than is available before any more marketing schemes affecting the food supply of the country are brought into being.
